There was not much outdoor work, said the same informant, to be done in visiting patients in their homes, but there was always a great crowd both of men and women at the surgery who came with minor complaints. His time was too largely taken up by insignificant cases, and it seemed to me from much confirmatory evidence that his position typified that of many of his colleagues. Such contract work has lowered the scientific standard of medicine and put a premium upon some routine of prescribing. Of course, it will be said that the evil must be increased where practitioners have too many names on their lists, but this does not occur in any marked way in Nottingham. It is true that some practitioners in Nottingham—not many, but a few—have lists of more than 2000 insured persons, and I found the opinion growing that it was nearly impossible to attend properly to such numbers, particularly when the frequent illness among the women workers is remembered. The heat in some of the lace factories and the nature of the work done generally appear to damage the normal appetite. These women, I was told, had no zest for their food, and consequently consumed a fabulous amount of pickles. Speaking generally, there is an unusual amount of minor sickness in Nottingham which greatly increases the work of the panel practitioners.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Medical School on its University and Clinical Side.

THE University session is now in full swing both at the University itself and at the various hospitals associated for teaching purposes with the medical school. The changes in the staff are comparatively few. The chair of clinical medicine, which remained unfilled for some time after the expiry of the term of office of Professor Judson S. Bury, has been filled by the election of Professor E. S. Reynolds to the office. The professor began his lectures this term. Dr. Graham Brown also began his work as lecturer on experimental physiology in the University. Special provision had to be made for instruction of those candidates preparing for the Diploma in Psychological Medicine granted by the University. The number of new entries for the University degrees exceeds that of last year. The number of women students seems to be on the increase.

A Better Manchester: The Housing and Sewage Problems.

There has lately been an urgent appeal in the lay press for a "better Manchester," and various suggestions have been made. The crux, however, is in the housing problem and the proper accommodation of the people. The sanitary committee has erected in the congested district of Hulme on land acquired some time ago 40 houses of two-storey cottage flats, consisting of living-room, one bedroom, and

scullery of good proportions, with the proper sanitary accommodation for each, and 50 cottages, each with a living-room, two bedrooms, and a scullery. The rental of the smaller flats is fixed at 4*s*. 6*d*. per week and of the larger 5*s*. 9*d*. per week. The estimated cost of the whole is about £16,000. Practically all the tenements have been let. The main drainage scheme promoted by the rivers committee of the corporation is steadily making progress. Besides improving the bed of the river Medlock the great drainage scheme is conceived on such lines that it will serve Manchester for another 50 years. The cost of the present extension will not be less than £1,000,000, and this, added to the previous expenditure by the rivers department, will make the total outlay equal to £2,500,000. The new sewers on the south side of the city are about a mile and furlong in length, diameter 3 feet, while the depth below the surface varies from 41½ feet at Stockport-road to 30 feet at Wilmslow-road. The work of construction is continued night and day, about 180 men being employed.

The Clergy on Sport and Recreation.

At a recent conference held in Manchester the attitude of the Church towards sport and recreation was discussed. One speaker expressed the opinion that recreation had become a danger because it was uncontrollable. Some games were surrounded by a bad atmosphere. The remedy was not to ban the game, but to clear the atmosphere. The Rev. F. H. Gillingham, vicar of Bordesley, and a well-known member of the Essex county cricket team, regretted that much of the sport to-day, instead of being a recreation, had become a huge financial concern; the evil of gambling had crept in, while the spirit of speculation was fanned by newspapers of a special class. To-day there was a tendency to develop a few specialists rather than to encourage the many to attain a higher physical standard. The primary idea of recreation as a means of counteracting the stuffy atmosphere of the office and the restricted chest was largely lost sight of in the mad competition for medals and cups. He suggested that it would be far better for the Olympic Fund to be used for buying playing-grounds near great cities. The clergy should go within the pale and take an intelligent interest in sport. Playing games helped a clergyman to keep fit, taught him to understand the men among whom he worked, and enabled him to exercise an influence upon the man with whom he played. The Bishop of Birmingham said he would rather that all the people he saw in the hall were able to run 100 yards in 12 seconds than that one of them should be able to do it in 9 4-5 seconds. —The Bishop of Carlisle (Dr. Diggle), speaking at the Old Mancunians Association, expressed himself as follows: "When people talk to me about working men going to football matches and kinematograph shows to get some sort of movement in life, all I can say is: My entire sympathies are with them, and if I lived their life of drudgery I should do the same. If you are to stop the emigration into the towns and across the seas you must in same way or another provide, not parsonic recreations, but the popular recreations which are produced by the people for the people."

Oct. 21st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

St. Luke's Day Service.

SUNDAY being the day after St. Luke's day there was a special service at St Luke's Church for medical men, at which there was a large attendance, many coming in their university and college robes. Among the non-medical members of the congregation were the Vice-Chancellor of the University of Liverpool and the chairman of the Liverpool Royal Infirmary Committee. An interesting and eloquent sermon was preached by the Bishop of Durham. The service was conducted by the Bishop of Liverpool, the Rector of Liverpool, and the Vicar of St. Luke's Church. The Bishop of Durham spoke of the claim the profession had to the grateful and reverent regard of the public, both on account of their skill and of their self-sacrificing service. He went on to relate his personal experiences during an illness, and paid a grateful tribute to his medical attendant and nurse. A collection was made on behalf of the Royal Medical Benevolent Fund, which amounted to over £30.

Electricity for the Continuous Sterilisation of Milk.

It is stated that Professor J. M. Beattie and Mr. F. C. Lewis are awaiting the necessary plant to complete their experiments on a commercial scale. The experiments began in 1911, and the investigators have established that the exposure of milk for a very short time to a high tension current caused effective sterilisation. The advantages of the process are that the milk is not heated unduly, no coagulation can occur, and a continuous stream of milk can be sterilised. All colon and allied bacilli were found to be destroyed, and there was an enormous destruction of bacteria of all kinds; the organisms left alive were, so far as could be traced, air-borne and non-pathogenic. Enzymes were not destroyed, milk-sugar was slightly increased, mineral matter slightly decreased, and the acidity calculated as lactic acid was very slightly increased in the sterilised milk. The taste of the milk was not altered. Both natural and artificial contamination with tubercle bacilli can be rendered harmless. The difficulties still to be got over are largely in the handling of the milk for distribution so that reinfection may be prevented.

Lease of the Abattoirs.

Repeated attention has been called to the presence of slaughter-houses in crowded areas in Liverpool. The matter of the lease of the Trowbridge-street abattoir and the trades connected with it comes before the city council this week, and the action taken by the city council is watched with much interest. The council of the Liverpool Medical Institution at a special meeting passed the following resolution:—

That this meeting reaffirms the view that it has already expressed, that the slaughtering of animals as carried on in the city is eminently undesirable and contrary to the interests of public health.

A copy of this resolution is to be sent to the town clerk.

Oct. 21st.

BRISTOL AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol.

AT a recent meeting of the council a resolution was passed expressing deep regret at the resignation of the chairmanship by Mr. Lewis Fry, Mr. George A. Wills being elected in his stead. The Vice-Chancellor reported that an offer of £5000 had been received from someone, who wished to remain anonymous for the present, towards the foundation of a residential college for men students, provided that the council saw its way to raise enough money to found a college for not less than 25 students. A report by the professor of chemistry shows that of 13 students who have obtained honours since the foundation of the University 10 are holding important research and industrial posts, the remainder being occupied in post-graduate investigations in Bristol.

Bristol Medico-Chirurgical Society.

At the annual meeting of this society Professor Walter C. Swayne resigned the chair to his successor, Dr. P. Watson-Williams, whose inaugural address dealt with the association between diseases of the nose and those of the eye. The remarks with which he opened his discourse included a brief sketch of the evolution of specialism in medicine. He showed that the orbit might become infected as a result of nasal disease through the maxillary antrum, the ethmoidal cells, or the frontal sinus; while antral disease might infect the lacrymal duct, and the optic nerve might become implicated in inflammations of the sphenoidal sinus. All these relationships were exemplified by some admirable lantern slides. Dr. Watson-Williams concluded his address by pleading for a more generous recognition of the need for special study of the upper respiratory tract and its diseases in the medical curriculum. The secretary and other officers presented their reports, which are not altogether reassuring from the financial point of view, though the membership is well maintained and the library is in a flourishing condition. The Vice-Chancellor of the University, Sir Isambard Owen, who was present, was able to give some interesting details as to the buildings in which the library will be housed when the projected extension of the University is completed. The premises which at present contain the books will have to come down to make room for the new buildings, but the

Vice-Chancellor assured his hearers that adequate accommodation would be found for the library during these changes. Two alterations were made in the rules of the society, one being designed to allow of the holding of afternoon meetings and the other to secure for the society's journal the right to publish all papers read at its meetings.

Sanatorium for Tuberculous Bristol Children.

Representatives of the health, education, and insurance committees of Bristol, in conjunction with the Civic League, are considering the foundation of a sanatorium for tuberculous children, and a house at Kingswood has been inspected with a view to converting it into a temporary sanatorium. It is hoped that this, or at any rate the permanent building, will include accommodation for cases of surgical tuberculosis, a matter in which Bristol, like many other cities, is wofully deficient.

Bristol Insurance Committee: Work of the Medical Referee.

The excellent work done by Dr. Bertram M. H. Rogers, the medical referee appointed by the Bristol Insurance Committee to consider cases of alleged malingering and kindred matters, has been mentioned in these columns from time to time. The Insurance Commissioners having suggested that Dr. Rogers's appointment should terminate, the Local Committee report that they consider this step inadvisable in view of the valuable work done by the medical referee, and also because the local panel was formed only on condition that a referee was appointed. They have put forward a temporary scheme to hold good till the Commissioners have established the matter on a permanent basis.

Barnstaple Guardians and Vaccination.

At the last meeting of the Barnstaple board of guardians a discussion took place in reference to a communication received from the Blackburn board of guardians on the subject of vaccination. The Blackburn board sought support for a resolution regretting that recent legislation had made the vaccination law practically inoperative, and asking the Government to appoint a committee to inquire into the carrying out of the clauses of the Act of 1905 relating to conscientious objectors. Eventually it was decided, by the casting vote of the chairman, to support the resolution of the Blackburn union.

Wilts County Asylum.

Mr. John Ireland Bowes, the medical superintendent of the Wilts County Asylum Devizes, has recently resigned his appointment after 30 years' service. During the period of time Mr. Bowes has been connected with the institution the building has been very largely increased, and the patients have more than doubled in number.

"Miners' Phthisis" in Cornwall.

At the last meeting of the Cornwall sanitary committee it was reported that during the years 1911, 1912, and 1913 (the last year having been averaged for the last three months), 382 deaths were caused by "miners' phthisis." These figures showed a slight increase during the past 11 years.

The Treatment of Pulmonary Tuberculosis.

The Somerset county council has decided to acquire a site for a permanent sanatorium at Dulcote, near Wells, at an estimated expenditure of £1660.

Presentation to a Medical Practitioner.

At St. Colomb (Cornwall) on Oct. 15th Mrs. Vyvyan, of Trewan, on behalf of the members of the St. Colomb Red Cross class, presented Mr. John Ronald Rigden Trist, L.R.C.P. Lond., M.R.C.S. Eng., with some medical books as a mark of regard and esteem for his services as honorary instructor.

Oct. 21st.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Royal Orthopædic and Spinal Hospital.

THE general committee in its annual report, to be presented at the annual meeting on Oct. 30th, points out that the time has arrived when the rebuilding of the hospital should be undertaken. The provisional scheme provides for the erection of a suitable building upon the present site, an increase of beds from 30 to 50, a modern equipment, and repayment of the mortgage debt on the out-patient department of £2800. The total cost is estimated at about £30,000. The committee points out that the present building is quite unsuited for the many operations performed, in which the most rigid asepsis is essential. The treatment of surgical tuberculosis, which forms a large proportion of the work, needs a building with a modern system of ventilation and lighting. The number of patients has scarcely been affected by the operation of the National Insurance Act—indeed, the number of in-patients and of operations has substantially increased.

Hospital Saturday Fund.

The total of this year's collection is £22,108 13*s.* 2*d.* Misunderstandings and unsettlement caused by the National Insurance Act accounted for upwards of 150 firms discontinuing the collection, at least temporarily, but the majority of these have now decided to continue their subscriptions. As in former years, it has been decided to distribute £10,000 among the various hospitals and nursing societies. The more important of the sums allocated are to the General Hospital £3150, Queen's Hospital £2100, General Dispensary £1010, Children's Hospital £800, Eye Hospital £350, Women's Hospital £500, Orthopædic Hospital £300, Ear and Throat Hospital £125, and Jaffray Hospital £400.

Oct. 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh School of Medicine for Women: Opening of New Anatomy Rooms.

IN connexion with the medical education of women in Edinburgh an important development was inaugurated on Oct. 18th with the opening of the new anatomy rooms for the Edinburgh School of Medicine for Women, Surgeons' Hall. The new anatomy room, which is situated at the back of the main block, measures 25 feet by 22, and has accommodation for six dissecting tables. The bone room, which is immediately behind the dissecting room, measures 22 feet by 10. The Principal, Sir William Turner, declared the rooms open, after a short address by the dean of the school, Professor William Russell, who has just been appointed to the Moncrieff-Arnott chair of clinical medicine in the University of Edinburgh.

Scarlet Fever Outbreak in Edinburgh.

Dr. A. M. Williamson, the medical officer of health, states that the outbreak, which last week appeared very threatening, 192 cases being reported in seven days, is now at an end. It lasted about a fortnight, and was limited to the south side of the town. The milk-supply, to which the source was traced, was cut off, and this step was immediately followed by a cessation of non-contact cases being admitted to the City Hospital. On Saturday last only one case was notified, and as things have now returned practically to the normal, the prohibitive order in connexion with the milk-supply has been withdrawn.

Edinburgh School Board and Physically Defective Children.

The board have purchased a piece of ground to the west of the city, adjoining the Gorgie School, roughly 1222 square yards in area, whereon they propose to erect a special school for physically defective children. A school of the same kind is in contemplation for the north side of the city. The net cost to the board for feeding necessitous school children amounted to £1861 5*s.* 6*d.*

Sanatorium for South-Eastern Counties of Scotland.

The Local Government Board recently received representatives from the county councils of the counties of Berwick, Haddington, Linlithgow, Midlothian, Peebles, Roxburgh, and Selkirk to discuss the terms of a draft order prepared by the Board providing for a combination of these counties for the erection of a sanatorium. It was arranged that a representative of the county councils should adjust with the Board the necessary amendments, and that when this matter is completed the draft order as amended should be submitted to the individual counties for their approval.

Inaugural Lecture of Professor T. K. Monro at Glasgow University.

Dr. T. K. Monro, the recently appointed professor of

medicine, delivered his inaugural address at the opening of the medical session last week at Glasgow University. The evolution in medicine, he said, was without doubt in an upward direction. The beneficent powers of medicine were being constantly enhanced, and the success already attained was very encouraging. He quoted Mr. John Burns, that in the three years 1909–11, 772,811 fewer deaths had occurred in England and Wales than would have occurred under the average death-rate of the years 1871 to 1880. Professor Monro indicated some of the steps by which medicine had been advanced and some of the problems urgently pressing for solution at present. It was no unreasonable optimism to hope that certain diseases which at present caused many deaths might be altogether abolished or reduced to a position of relative insignificance. He instanced scurvy, leprosy, small-pox, malarial fever, and typhus fever, and the enormous reduction in the prevalence of tuberculosis in England and Wales since Queen Victoria came to the throne and in Glasgow during the last half century. He suggested that by coöperation between the health authorities, the medical profession, and the lay public, an enormous reduction might be made in the annual mortality of Glasgow. He discussed the varying degrees of respect with which the profession had been regarded at different periods of history, and emphasised the importance of cultivating the art of observation and the value to medical men of what was called a good manner.

Robroyston Hospital, Glasgow.

The Glasgow corporation have asked for tenders for erecting the first block of the infectious diseases hospital at Robroyston, at an estimated cost of £60,000. The hospital is intended primarily for cases of small-pox, but when none is present it may be used for the isolation and treatment of cases of tuberculosis.

Insurance in Aberdeen.

There are still 2500 persons in Aberdeen who have not as yet chosen their doctor under the National Insurance Act. The Medical Benefit Committee has decided that patent medicines should not be prescribed under the Act.

Aberdeen Poor-house Hospital Report.

In his report on the Aberdeen Poor-house Hospital at Oldmill, Dr. Thomas F. Dewar, medical inspector of the Local Government Board, Edinburgh, remarks that the institution seemed clean and bright, and impressed him as being up to the standard of a general hospital. One ward on the ground floor contained epileptic patients, another cases requiring surgical dressings, ulcers, and the like. Phthisis was treated in wards set aside for that purpose. Both the female and male venereal disease wards were empty. About 30 confinements occur in the hospital per annum. The operating room was extremely satisfactory, although there had been so far only about five operations in it. The infants and older children were well nourished and browned with the sun. One child recently cured of lupus in the cheek seemed to owe its recovery to sun treatment.

Oct. 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal College of Physicians of Ireland.

AT the annual meeting of the Royal College of Physicians on Oct. 18th (St. Luke's Day) Dr. C. E. FitzGerald was re-elected for a second term of office, and the other College officers were elected. In the evening the festival dinner was held in the College Hall, and was partaken of by some 29 Fellows and 70 guests. Dr. James Little proposed the toast of "The Guests," to which the Lord Chancellor of Ireland and the President of the Royal College of Surgeons in Ireland replied.

The Annual Report of the Local Government Board.

I may be permitted to supplement your notice of the annual report of the Local Government Board for Ireland[1] by reference to one or two other points of interest. According to the figures quoted there has been a steady decrease in pauperism for several years past, amounting to nearly 25 per cent. in five years. The total number of persons who received indoor or outdoor relief in 1908–9 was 102,587; in 1912–13 it was 77,726. In March last 2589 children were boarded out by Poor-law guardians, while there were still 7438 in workhouses. A very pleasing feature of the boarding-out system is that in many cases the children are adopted by the foster-parents and treated as if they were really members of the family, the children gaining all the advantages of kindly homes. The rate of infant mortality in the workhouses is very high. During the year 791 deaths occurred of infants under 1 year of age. Nursing in workhouses is not yet in a satisfactory state; there are still 12 workhouses in which no trained nurse is employed. The salaries of dispensary medical officers, together with the remuneration paid to temporary medical officers, amounted to £121,801, as against £120,068 in the previous year. 92 unions have now adopted scales of salaries, more or less adequate, for their medical officers. As the Board states, "much yet remains to be accomplished." There was an increase from 165,262 to 171,793 in the number of new cases attended by dispensary medical officers at the patients' homes, and a decrease from 487,516 to 476,931 in those attended at dispensaries. There was a decrease from 77,379 to 69,480 in the number of vaccinations and revaccinations performed. This is due to the failure of guardians in many instances to carry out the laws governing vaccination as part of a campaign against vaccination. The Local Government Board has been content to "deplore this attitude on the part of responsible local authorities, and warn them of the serious responsibilities in which they will become involved should an epidemic of small-pox occur in their districts." The activity of the Board in regard to tuberculosis is hardly so real as might be inferred from perusal of the report. The Board, for instance, deplores that notification of tuberculosis is not compulsory throughout the country, and as an instance of the inefficiency of the present system states that in both Dublin and Belfast the notifications fell short of the number of recorded deaths from phthisis. What the Board omits to mention is that this is a necessary result of the order issued by the Board itself to govern notification in Dublin and Belfast, and the other areas which adopted Part I. of the Tuberculosis Prevention Act (1908). By that Act the Local Government Board was empowered to prescribe under what conditions notification was to be practised. The order issued was to the effect that notification should only be made in cases of tuberculosis of the lung, at any stage at which the sputum was, in the opinion of the practitioner in attendance, liable to communicate the disease; and further, only when the patient habitually slept or worked in the same room with another person not similarly affected, or was employed in handling, preparing, or distributing milk, meat, or any articles of human food intended for sale to the public. It is obvious that notifications limited by such conditions can furnish no information of value either for statistical or sanitary purposes. Again, the Board has adopted a strange attitude with regard to domiciliary treatment under the sanatorium benefit. Instead of dealing with the question in a general order as was done in England the Board has directed that each individual case where it is proposed to give domiciliary treatment is to be reported and dealt with on its merits. The result has been to place grave obstacles in the way of this form of treatment.

Dublin Slums.

The Lord Mayor of Dublin has announced that, following a deputation from the Irish Association of Municipal Authorities, the Secretary for Ireland is about to appoint a Departmental Committee to inquire into the nature and extent of the slum problem in Dublin.

The Abbey Sanatorium, Belfast.

The Belfast board of guardians has agreed to the transfer of the Abbey Sanatorium to the city corporation as and from Oct. 1st, 1913, subject to the terms being satisfactorily arranged between the two bodies and a proper agreement being drawn up embodying the terms agreed upon, and the matter is at present being considered by subcommittees of each of these bodies.

Scarlet Fever Epidemic in Belfast.

At a meeting of the Belfast board of guardians held on Oct. 14th attention was called to the widespread, continuous, and alarming outbreak of scarlet fever in Belfast. It was stated that, in addition to the ordinary municipal fever hospital at

[1] THE LANCET, Oct. 4th, p. 1018.

Purdysburn, where there are now over 200 patients, the Poor-law hospital at the Belfast workhouse contained on the day the guardians met 172 cases. It was directed that the recommendation of the infirmary committee should be sent to the city corporation, viz. :—

That the city corporation should make provision for the reception of cases of scarlatina which are being received into the workhouse, of which there has been a high number for many months.

Death of Surgeon-Major Robert Dick, I.M.S. (ret.).

I regret to announce the death, at the advanced age of 82 years, at his residence, Garry, Ballymoney, co. Antrim, of Surgeon-Major Robert Dick, M.D. Q.U.I., F.R.C.S. Eng., on Oct. 14th. The son of Mr. Robert Dick, of Garry—an extensive farmer—the deceased was educated at Ballymoney, and subsequently at Queen's College, Belfast, having entered that institution as a scholar in the year it was founded, 1849–50. A contemporary scholar was the late Professor James Cuming, M.D., and another fellow student (who entered the next session) was the celebrated Sir Robert Hart, Bart., who was the most decorated man of his time. Dr. Robert Dick was a scholar all through his college career, and in 1853 he graduated in the Queen's University of Ireland, taking his M.D. with honours. He afterwards became a Member and Fellow of the Royal College of Surgeons of England. He early entered the medical service of the Old East India Company, which afterwards became merged into the Indian Medical Service. In his early career in the East he took part in the Persian campaign, and later he passed through the Indian Mutiny. Afterwards he was stationed at Poona, but his health becoming impaired he retired on pension 41 years ago, and in after years he lived quietly at his residence at Garry, Ballymoney, taking very little interest in outside affairs. He was buried on the afternoon of Oct. 16th in the Old Church Burying Ground, Ballymoney, a large number of relatives and friends paying him the last tribute of respect. The deceased was unmarried.

Serious Charge against a Nurse.

At an inquest held in Belfast on Oct. 18th in reference to the death of a young woman, aged 24 years, which occurred on Oct. 16th after childbirth, the jury found that death was caused by puerperal septicæmia due to carelessness and want of skill on the part of the nurse. The coroner said he was determined to put down unskilful nursing, as the National Insurance Act provided for proper maternity treatment. The deceased woman was confined on Oct. 10th, the nurse attending. On the 13th a medical man was sent for, as the woman did not seem to improve, and he advised her removal to hospital, but she was unwilling to go. On the 15th another medical man saw her, and she was removed to the Maternity Hospital late at night, where she died next day.

Resignation of Mr. Thomas Leary.

Mr. Thomas Leary, J.P., one of the best-known medical men in the North of Ireland, has, after almost 52 years' service, resigned his post as medical officer of Castlederg and Killeter (No. 1) District Dispensary, co. Tyrone. On Oct. 17th the Castlederg board of guardians passed unanimously a resolution regretting Mr. Leary's resignation, and recording their appreciation of his long and faithful services.

Oct. 21st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The International Congress on First Aid and Ambulance Work.

(*Concluded from p. 1027.*)

AT the closing sitting of the Congress it was decided to elect an international committee for first aid, which would devise means for effective coöperation in the event of great disasters, such as earthquakes, floods, epidemics, conflagrations, and the like, and for giving prompt assistance to sufferers, just as the Red Cross societies do in war time. After the Congress was over numerous members decided to stay in Vienna for another few days, for on Sept. 19th the Congress of the German Naturalists and Medical Men took place, and proved an important and interesting meeting.

Resuscitation of Persons Apparently Dead from Various Forms of Asphyxia.

Dr. Kuhn, of Berlin, discussed this subject, which forms the basis of many gruesome stories of persons having been buried alive by mistake. His paper emphasised the necessity of applying modern methods of first aid (artificial respiration and electrical stimulation of the heart) more extensively than hitherto, especially in cases of apparent death from the action of poisonous gases, such as carbon dioxide or carbon monoxide, or from submersion in water, or from electric shock or lightning stroke. Efforts for resuscitation ought not to be hastily abandoned, for even after hours of prolonged work the result may be successful, since experiments conducted by Kuliabko and Hering have shown that human hearts removed on the necropsy table could be made to beat from 8 to 11 hours after death.

The Dangers of Sponge-fishing.

Dr. Flégel, of Crete, said that the use of modern methods in sponge-fishing increased the danger of this occupation. Some 100,000 persons were engaged in it, especially off the coasts of the Mediterranean and Adriatic. The ancient methods of working either with a trident or a search-rope, or when naked divers were employed, required the work to take place in shallow water. The modern methods, involving the use of diving apparatus at great depths, caused much loss of life. The Governments of Austria-Hungary and Egypt had recently prohibited these methods, but in Greece, Tunis, and Turkey the sponge-gatherers had no protection by law and no sufficiently strict regulations.

First Aid on the Austrian State Railways.

Dr. Bogden, the chief medical adviser of the Austrian State railways, read a paper on the Organisation of First Aid on the State Railways in this country. He said that boxes containing first-aid outfits were now available on each express train, and at each important station or junction such an emergency case was ready for use. Instruction in applying first aid was given to the railway servants and officials in special Samaritan classes. Hospital cars and ambulance cars have been added to the rolling-stock of the State railways, so that each district railway office can be supplied with them at very short notice, and special cars have been built for the conveyance of infectious patients. The recent political complications have had the effect of causing the arrangements in this respect to be brought to a high degree of efficiency.

Regulation of the Admission of Patients to the Hospitals.

The difficulties of finding a bed for a patient requiring first aid in hospital were well illustrated in a paper by Dr. Hofmokl. He said that in consequence of the great number of persons seeking admission to hospitals, and the relative scarcity of beds, especially in the large towns, it was necessary to secure a bed in one of the charitable institutes or in a hospital before the patient was brought there. Especially in cases of accident, suicidal attempts, and the like, it was not possible to take a patient from one hospital to another in search of a vacancy. Here co-operation of the police, the ambulance corps, and the hospital boards was necessary. In Vienna there was a special administrative office, which kept account of the vacancies in all the Vienna hospitals, and was informed by telephone as quickly as possible whenever a hospital bed became vacant or was reoccupied. Through the agency of this office a bed might be secured by the police, by the first-aid ambulance, or by practitioners, but in order to avoid abuse a patient who had had a bed secured for him without real necessity might be dismissed at once by the hospital medical officer. A decentralisation of the conveyance of sick persons was necessary in large towns, and it was desirable that special vehicles which could be disinfected after use should be provided more frequently than at present for the removal of infectious cases.

First Dressing of Injuries.

A number of papers dealt with the first dressing of injuries, a subject which has received much attention during the recent war in the Balkan regions. The experience gained during the great battles of these campaigns was embodied in a paper entitled "First Aid on the Battlefield," in which it was recommended that wounds should receive aseptic dressing, after using tincture of iodine freely on

and around the injured parts, and after checking hæmorrhage. All major surgical interference should take place in a well-equipped hospital, after the shock of transport had subsided. Another paper by Dr. Rosner, of the Vienna Rettungsgesellschaft, dealt with the ordinary injuries of every-day life. He advised that such wounds should be neither probed nor touched with the fingers, and that prolapsed organs should not be replaced but carefully supported. The washing out of injured parts ought not to be undertaken when first aid was given. A soft, pliable, absorbent, and aseptic material (absorbent sterile gauze) was the best dressing for all purposes; it could also stop hæmorrhage if applied with a proper degree of pressure. Immediate immobilisation after reducing a fracture or a dislocation should take place before removal of the patient. It was very important that the first dressing should be most carefully applied, as it often determined the fate of the sufferer.

The Increase of Suicides.

A lamentable fact was clearly brought out by Herr Wortmann, of Vienna, in a paper on Suicides and Attempts at Self-destruction. He said that there was a constant and steady increase in the number of persons who deliberately took their own lives. Various reasons have been assigned for this social abnormality, but no satisfactory explanation has been given. Mental depression seemed to be present in each case, and attempts to strengthen the will-power of weak-minded individuals (anti-suicide societies) appeared to have been beneficial in some instances. It was a singular fact that the number of suicides increased in summer and during the bright months, from May to August, at least in this city, where 1387 cases were attended to by the Rettungsgesellschaft last year. Herr Wortmann attached much importance to the collection of statistics from all civilised countries as to the motives for suicide, and denounced the modern system of education, which, he said, did not go far to produce strong characters, but rather tended to cause nervous breakdowns.

Prevention of Panic among the Audience at Public Entertainments.

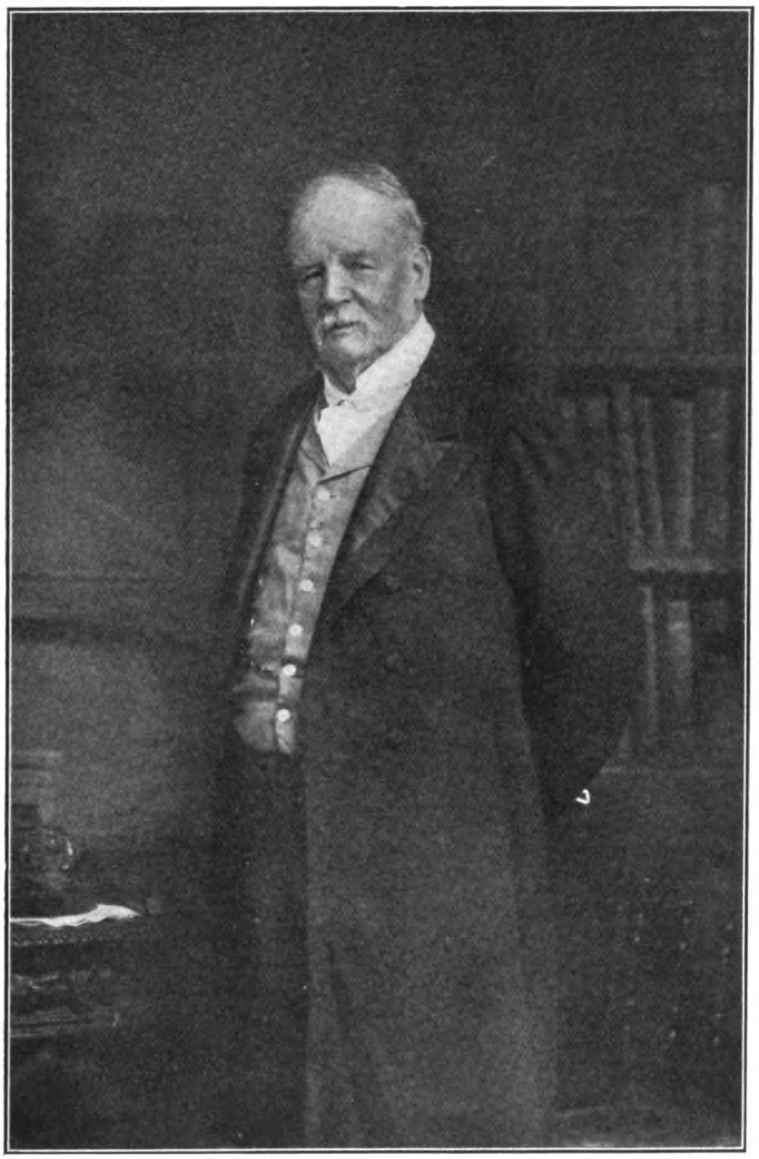
An interesting paper by Herr Greil summarised the modern view of the requisites for the safety of a crowded audience in public buildings. He strongly recommended that such buildings should be made fireproof; that the stage should be separated from the rest of the house by an iron curtain; that only electric light should be used, and that the current for this purpose should be derived from two different sources. No tenements or flats should form part of these buildings or be annexed to them. Heating should be by means of hot air, hot water, or steam. No smoking should be allowed while entertainments were in progress, and a detachment of firemen should be in attendance at each performance. The building should not contain more than three persons per square metre, and for every 100 visitors one gate or door should be provided. Good ventilation, a supply of pure drinking water, and sufficient lavatory accommodation were also required.

Oct. 18th.

ROYAL DENTAL HOSPITAL OF LONDON. — The annual dinner of the staff and past and present students will be held on Saturday, Nov. 22nd, at 6.30 for 7 o'clock, at the Hôtel Métropole (Whitehall Rooms), under the presidency of Mr. Rees Price. Applications for tickets should be made to the Dean at the Royal Dental Hospital, 32, Leicester-square, London. The medical committee will be "At Home" to all old students of the hospital on the same day from 2.30 to 5 P.M.

RANKING MEMORIAL, TUNBRIDGE WELLS.— In connexion with the memorial in the Tunbridge Wells General Hospital to Dr. J. E. Ranking a bed has been endowed, and instead of a medallion portrait as at first decided upon a statuette is to be provided. Any balance of the money subscribed will be devoted to the Samaritan Fund, which exists for the benefit of those patients who, though well enough to be discharged from the hospital, need to be sent to a convalescent home or to be assisted in some other way.

Obituary.



SIR JOHN BATTY TUKE, M.D. EDIN., F.R.C.P. EDIN., F.R.S.E., LL.D., D.SC.,

FORMERLY REPRESENTATIVE OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH ON THE GENERAL MEDICAL COUNCIL AND M.P. FOR THE UNIVERSITIES OF EDINBURGH AND ST. ANDREWS; MORISON LECTURER ON INSANITY AND MENTAL DISEASES.

Sir John Batty Tuke died at his residence, Balgreen House, Edinburgh, on Oct. 13th, in his 79th year. He was born at Beverley, Yorkshire, on Jan. 9th, 1835, being the eldest son of John Batty Tuke of that town, and received his academic education at the Edinburgh Academy and his professional education at the University of Edinburgh. He qualified in 1856 as L.R.C.S. Edin., and took his M.D. degree at the University in the same year. He went to New Zealand in 1857 as civil medical officer to the 65th (2nd York. N. Riding) Regiment, but on the outbreak of the Maori war in 1860 he became senior medical officer of the Colonial troops, serving until the end of the war. In 1863 he returned to Edinburgh and entered on practice, becoming assistant physician to the Royal Edinburgh Lunatic Asylum. In 1865 he was appointed medical superintendent of the Fife and Kinross District Lunatic Asylum, where he remained until 1873 when he returned to Edinburgh and entered on the practice of mental diseases, in which he had already acquired a recognised position, for in 1865–66 he published in the *Edinburgh Medical Journal* his essays on the Insanity of Pregnancy, Puerperal Insanity, and the Insanity of Lactation, and in 1869, in conjunction with Professor Rutherford and in the same journal, a remarkably acute study of the morbid appearances met with in the brains of 30 insane persons, wherein he helped to lay the foundation for the modern doctrine of a physical basis as underlying all mental aberrations. He also published in 1873 his work on the Morbid Histology of the Brain and Spinal Cord as observed in the Insane, and in 1874 was appointed Morison lecturer on insanity at the Royal College of Physicians of Edinburgh, whose Fellowship he had received in 1871. At this period he became associated in the management of the Saughton Hall Asylum at Edinburgh. He remained director of this asylum until on the removal to a new site a few years ago he was succeeded by one of his sons, Dr. J. Batty Tuke. His influence had much to do in hastening the more enlightened and humane methods of dealing with the insane which characterise modern practice. In 1894 he delivered the Morison lectures on the Insanity of Over-exertion of the Brain, giving rise to the appreciation of what is now known as "brain-fag." He also contributed the articles on Insanity and Hysteria to the ninth edition of the Encyclopædia Britannica.

Sir John Batty Tuke's public work included the representation for 25 years of the Royal College of Physicians of Edinburgh on the General Medical Council, and of the Universities of Edinburgh and St. Andrews in the Parliaments of 1900 and 1906. He retired from Parliament in 1910. In 1898, while he held the office of President of the Royal College of Physicians of Edinburgh, he received the honour of knighthood. He had been President of the Neurological Society of the United Kingdom. In 1896 the University of Dublin conferred on him its honorary D.Sc. degree, and in 1912 the Universities of Edinburgh and St. Andrews recognised his services to them in the House of Commons by conferring on him their honorary LL.D. degrees. He was also a Fellow of the Royal Society of Edinburgh.

Sir Thomas Clouston sends the following appreciation:— "Sir John Battty Tuke was one of the first men in Great Britain in the late 'sixties' and early 'seventies' to use the new histological methods of staining and section-cutting of the brain in the insane, and this gave a great impetus to the study of the pathology of our department in Scotland. His work still stands. He had the true instinct to see what was being done to advance normal histology in the anatomy and physiology department of the University of Edinburgh, and became acquainted with the methods used by John Stirling and Professor Rutherford. His clinical contributions to psychiatry in regard to the insanities connected with pregnancy were sound and practical. In those he followed the lines of the Morningside School of Skae, as also in

SIR JOHN BATTY TUKE, M.D. EDIN., F.R.C.P. EDIN., F.R.S.E., LL.D., D.SC.,
FORMERLY PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

(From a photograph by Messrs. Elliott and Fry, Ltd.)

extending the 'open door' idea in the Fife Asylum. His Morison lectures on 'The Insanity of Over-exertion of the Brain' contained much original thinking and valuable practical suggestions in regard to the importance of rest in the treatment of some of the acute insanities, suggestions that are now universally accepted. He took large views in his scientific work and not those of a narrow specialism. It was this quality of mind that led him to establish the Pathological Club when he came to Edinburgh from Fife in 1873. That club, with its informal but fresh methods, drew together and stimulated many of our young pathologists in Edinburgh. It has been fertile in good results. He was an outstanding figure from the first in the College of Physicians and medical societies in Edinburgh. He appeared in the art, literature, and law circles in the city. He always kept up the dignity of medicine, and would allow no man to disparage or to take undue liberties with him. He was a loyal friend and a formidable opponent. Undoubtedly his greatest work in Edinburgh was persuading the College of Physicians to use some of its abundant funds to establish a laboratory where all the Fellows and many of our young scientists could work without cost and under the direction and stimulation of the superintendent, Professor Sims Woodhead. The results of the work in that institution in physiology, pathology, medicine, and surgery have been for Edinburgh almost epochal. Tuke's reputation as its originator will always stand on the secure foundation of the solid work accomplished there."

An Edinburgh correspondent writes: "Sir John Batty Tuke's work in the field of the pathology of insanity was in many respects remarkable. He was a pioneer in the practical study of the subject in this country, being one of the first to apply the microscope to the investigation of morbid changes in the nervous system. Working at a time when histology was still in its infancy, he made many original observations that are now established facts of neuropathology. He anticipated by 37 years the elaborate work of Cerletti upon the convoluting of the intracerebral arterioles, and there can now be no doubt that the abnormal appearances of the brain which he described more than 40 years ago as 'miliary sclerosis' are to be identified with the condition that has recently been the subject of so much investigation and discussion under the name of *senile plaques*, although he was unable with the methods at his disposal to distinguish clearly this genuine morbid alteration from others of an artificial nature that frequently simulated it. He was the first to insist upon the anatomical unity of the arachnoid and pia mater, basing his contentions upon personal observations and arguments that remain valid. He also recognised, far in advance of his contemporaries, the important applications of bacteriology to the elucidation of the pathology of the insanities."

Sir John Batty Tuke married in 1856 Lydia Jane Magee, a sister of the Rev. Dr. Magee, subsequently Bishop of Peterborough and Archbishop of York. Lady Tuke survives him, as do also his three sons, two of whom are members of the medical profession.

PROFESSOR ROBERT KUTNER, M.D. BERLIN, C.V.O.,

DIRECTOR OF THE KAISERIN FRIEDRICH HAUS, BERLIN.

THE news of Professor Robert Kutner's death will come as a shock to all interested in the post-graduate movement, of which he was one of the pioneers and guiding spirits. Kutner was born in April, 1867, at Ückermünde, where his father was a district practitioner. After completing his gymnasium course he commenced the study of medicine at Kiel, later on—with that freedom which under the German system is permitted to all medical students—attending the Universities of Berlin and Freiburg. After graduating M.D. at Berlin he became interested in urology, and studied for a time under Guyon at Paris, Nitze at Berlin, and Dittel at Vienna, learning by personal experience the value and usefulness of graduate teaching. In 1891, having gained his "Approbation," he commenced practice at Berlin as a specialist in genito-urinary diseases, a specialty to which he continued faithful to the end. But it is as the pioneer of the graduate movement in Germany that he will be best remembered. It was Kutner who enlisted the helpful interest of Professor von Bergmann and Professor Althoff in favour of his ideal to make Berlin a gigantic centre of post-graduate study, with a central bureau, a definite, permanent graduate study institution, and affiliated institutions all over the Empire. That ideal, visioned by a young specialist who had not yet attained his thirty-first year, has since been amply realised in the establishment of the Kaiserin Friedrich Haus on the Luisenplatz, the recognised centre of the graduate movement, and one of the finest of modern German scientific institutions. It was Kutner, too, who initiated the movement for the establishment of an International Committee, finally appointed by the Vienna Congress. It was he, also, who founded and edited the *Zeitschrift für Aerztliche Fortbildung*, which is to-day one of the best and most readable of the many German professional papers, and is almost a model paper for the general practitioner. As director of the Kaiserin Friedrich Haus, secretary of the International Committee, and editor of the *Zeitschrift*, he was in constant touch with the movement. His knowledge of English, French, and Italian, his personal charm, unfailing tact, and genial personality, of which a cheery optimism seemed to be the main characteristic, made him an ideal head for the central bureau. Here in his little sanctum he was always ready to receive visitors. He gave his time unstintedly to help those who needed advice with regard to centres for study, courses, lecturers, or special facilities; he kept in close touch with all the various branches, and his counsel was always given after a careful consideration of individual wants and tastes. The energy and enthusiasm which he expended on his work in promoting the movement were almost phenomenal. He had an insatiable appetite for information with regard to the various developments of the movement, and personally visited every centre in order to draw up a handbook which should be authoritative and complete. In his own specialty, urology, he won deserved recognition, though his work on behalf of the graduate movement prevented him from giving to it all his time and attention. His efforts have been fittingly recognised both in Germany and elsewhere. On his professional attainments he gained his professorship; his work for the institute with which he was so closely connected won him distinctions from the State, while in England his efforts on behalf of the movement for graduate study were recognised by the grant of the C.V.O. But the distinction he valued most was the cordial recognition his efforts had received from the profession in all civilised countries, Japan among them, and the grateful appreciation rendered by the many graduate students whom he helped. His last illness was of short duration, and his death, on Oct. 5th last, came with the shock of an unawaited disaster. The funeral oration was delivered in the Kaiserin Friedrich Haus five days later by his life-long friends Professor Waldeyer and Dr. Albert Moll. His death is a loss to the movement for which he attempted and achieved so much—a loss which seems irreparable, since it is difficult to see who can adequately replace him.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Eduardo Wilde, the Argentine Minister to the Spanish Government. He was doctor of medicine and surgery of the Buenos Aires Faculty, and was professor of hygiene in the University. He wrote various works—Tiempo Perdido and Por Tierras y por Mares, and some thirteen years ago decided to give up his chair and devote himself to diplomacy.—Dr. Sota y Lastra, director of the Seville School of Medicine, a well-known laryngologist.—Dr. A. von Seeger, surgeon-general, of Leipsic.—Professor von Bälz, privy court councillor, of Stuttgart.—Dr. Dirr, court councillor, of Rosenheim.—Dr. Edward Schaer, professor of pharmacy in the University of Strasburg, and formerly professor in Zürich, aged 70.—Dr. Otto Lange, ophthalmic surgeon to the Ducal Hospital, Brunswick, aged 60.—Dr. H. Schwann, sanitary councillor, of Gudesberg.

SCHOOL MEDICAL SERVICE OFFICERS.—The first meeting of the group of officers engaged in school medical service, recently formed within the Society of Medical Officers of Health, will take place at the offices of the society, 1, Upper Montague-street, Russell-square, London, on Friday, Nov. 7th, at 5 P.M.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

White Bread.

HYGIENISTS have long called attention to the serious consequences of the increasing popular preference for white bread. At present dark-coloured bread is despised as "peasant's food"; in the towns the meanest workman will eat only white bread. The flour used for making this bread is obtained by passing the meal through a very fine sieve, so that it contains hardly anything but starch and cellulose. White bread, which plays an important rôle with the French people, is thus extremely poor in really nourishing food, and it is to the increasing consumption of it that many hygienists ascribe in France the racial enfeeblement, the diminution of stature, and even the present development of tuberculosis. Representations have frequently been widely made on this subject but without effect, for the bakers can provide only what the public demands. Matters have become still worse now that the grain is ground no longer by millstones but by steel rollers. The small country mills operated by a water-course or by wind are disappearing from day to day, and with them the millstones which more completely grind the grain, so that the glutinous layers of the husk were ground with the farinaceous part. Now the flour mills that have been developed by the great industry use steel rollers exclusively, which furnish a flour that sieves easily, and is all the whiter in that it contains hardly anything but starch. Dr. Monteuuis, in a recent communication to the Société de Thérapeutique, estimates that this sifting, casting away as it does the most nutritive part of the grain to the animals, represents for France a waste amounting to 400,000,000 francs a year, to which logically should be added the loss caused by the numerous diseases of nutrition due to the use of this bread—called usually "pain riche," but which from a hygienic point of view is rather "pain pauvre." The mischief is emphasised when, as is so often the case, bread is a very considerable portion of the diet.

Vincent's Antityphoid Vaccine.

The antityphoid vaccine prepared at the laboratory of military medicine of the Val-de-Grâce by Professor Vincent, in consequence of the excellent results on the French troops, reported from Morocco, has been used by the Italian military service in the Tripolitan army of occupation, which is decimated by typhoid fever. The statistics prepared by M. Cavallerleone, Médecin Inspecteur Général of the Italian army, have been communicated to Professor Vincent, who has published them. They show a very clear advantage in favour of Vincent's polyvalent vaccine prepared by the cold method of sterilising the cultures by means of ether. This vaccine has been used simultaneously with that of Pfeiffer and Kolle, a German vaccine sterilised by heat. Upwards of 16,500 soldiers have been inoculated. In 963 the heated vaccine of Pfeiffer and Kolle was used in three injections, in 1759 in two injections, and in 1960 in one injection. Vincent's vaccine demands four injections, but 4736 persons received only one, 3668 two, and 3105 three; in no case were the prescribed four injections administered for lack of time caused by the sudden departure of the troops. That is to say, Vincent's vaccine has not been administered as fully as it should have been to enable a fair comparison with the results obtained in Morocco by full injections. In spite of this, the 3105 soldiers who received three doses of this vaccine furnished only one case of typhoid fever, or 0·3 per 1000, without a death. Those vaccinated according to full requirements with the vaccine of Pfeiffer and Kolle gave 1·04 cases per 1000. The soldiers experimented on were quartered in places where their sanitary environments were similar—Derna, Bengazi, Tnara, Homs, Tobruk, and Tripoli. Many of the cases were not instances of infection with Eberth's bacillus, but with paratyphosus A or B, which explains the superior results, even with an insufficient technique, of Vincent's bacillus, which is polyvalent.

Death of Dr. L. Wickham.

Dr. L. Wickham has died at the age of 53 years. He was physician to the Hôpital des Vénériennes, an annex of the prison of St. Lazare, and was well known by his very interesting work on the application of radium to the treatment of angiomata and neoplasms of the skin. His work in collaboration with Dr. Degrais and his photographs of patients aroused considerable interest at the International Medical Congress in London recently.

THE MEDICAL CURRICULUM.

To the Editor of THE LANCET.

SIR,—In your interesting review of the present position of medical education in London in THE LANCET of Oct. 11th, p. 1071, you repeat a statement which has been made with some frequency of late—that the average time taken by a medical student at the present time to obtain a registrable qualification is no less than seven years. Because I felt sure that this figure was an over-statement I have examined the records of those students who have taken out the entire curriculum at Guy's Hospital during the five years 1909–13, leaving on one side the students of the older universities whose period of study is lengthened by the circumstance that with few exceptions an arts degree is taken in addition. The result shows that the average length of time of these students—and I have included both those who have taken the M.B. degree of the University of London and the diploma of the Conjoint Board—amounts to six years and two months. 23·3 per cent. took seven years or more than seven years; 76·7 per cent. took less than seven years; and 49·6 per cent. took six years or less than six years.

From these figures no deduction is made for absence on account of ill-health. The total amount of sick leave becomes considerable if it is remembered that we are dealing with a period of six years, and that the curriculum is so full that if a student misses some important part of a course or of a particular appointment in the wards the accident is almost certain to prevent him from completing the curriculum within the minimum time. Nor do the figures take into account the extra time spent by a proportion of the best students in preparing for such higher examinations as the Primary Fellowship of the Royal College of Surgeons or the B.Sc. of the University of London.

I do not doubt that figures prepared from other London schools would show a similar result, and that, so far as London students are concerned, the statement that the average time amounts to seven years is over the mark. I think it is the experience of those schools which have substituted annual payments for a single composition fee that the effect has been markedly to curtail the time spent on the curriculum. The incentive to secure qualification is much greater when failure entails the payment of further fees than when the hospital undertakes to teach the student for the same fee, even though qualification is delayed for ten years or longer.

I am, Sir, yours faithfully,

H. CHARLES CAMERON, Dean.

Medical School, Guy's Hospital, S.E., Oct. 15th, 1913.

THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—About 30 years ago one of our great surgeons, the late Sir Patrick Heron Watson, of Edinburgh University, used to teach the students that they must treat the primary and secondary manifestations of syphilis with the greatest care, as they arose, by means of local mercurial applications, and that only when absolutely necessary to cure special serious symptoms should mercury be given internally, but that on no account must a course of mercury be given with a view to prevent the occurrence of manifestations of syphilis at a future date. Treated in this way, he considered that an attack of syphilis was not more serious than an attack of measles—in each serious sequelæ might occur, but in each only in a small minority of cases. One of the great physicians, the late John Syer Bristowe, about 30 years ago, in his text-book on medicine, says:[1] "It is admitted now that mercury does not prevent either secondary or tertiary

[1] Bristowe's Theory and Practice of Medicine, fifth edition, 1884, p. 263.

symptoms from coming on; but, nevertheless, it is certain that it has a marvellous influence in causing the removal in turn of the primary, secondary, and tertiary lesions of the disease ..... the treatment should be continued until the lesions have disappeared under its influence, and even for a week or two longer."

About 37 years ago the greatest authority on syphilis, the late Sir Jonathan Hutchinson, advised a course of mercury to be given for six months to all patients in the primary and secondary stages of syphilis (one or two grains of grey powder in the form of a pill three times a day).

At a great discussion on syphilis at the Pathological Society in April, 1876, Sir (then Mr.) Jonathan Hutchinson is reported in THE LANCET[2] to have said: "How long after the secondary stage is it possible for syphilis to be transmitted hereditarily? ..... Now I have for long made it a rule, when consulted on this point, to insist that, before marriage, a period of two years should elapse from the last of what I have considered blood symptoms. I have given this opinion to a great many persons, and may confess that it has been a constant source of anxiety lest some day some one should bring me a snuffling, spot-covered baby, and say: 'See here, you said I might marry; just look at this.' Such an occurrence has, however, never yet happened to me." Earlier in his speech Mr. Hutchinson had said: "In a case in which mercury was begun early and continued for six months, I have known the rash, which would otherwise have come within six weeks, deferred to the end of the period named. ..... I feel sure that, in certain cases in which it fails to cure, it may greatly protract the malady by increasing the distance between its stages." Now in THE LANCET of Sept. 27th, 1913, p. 917, Major H. C. French, R.A.M.C., quoted with approval: "12. The marriage of syphilitics discouraged by law under ten years from date of contracting the disease." Why is ten years necessary? Sir Jonathan Hutchinson advised two years from the last of what he considered blood symptoms. The answer is that Sir Jonathan Hutchinson was speaking of cases which had either not been treated by mercury or had had a course of mercury for only six months, but it has now become the fashion to give long courses of mercury for two, three, or more years, and this doubtless retards the secondary stage and renders it necessary to postpone marriage.

In the above quoted discussion Mr. Hutchinson said: "With regret I admit that I have never seen with my outward eye the cryptogamic germ-poison of syphilis; but to my mind's eye it is as certainly present as if I had." Now that the germ, the spirochæta pallida, has been seen, this does not, of course, in any way alter the action of mercury on the manifestations of syphilis. The fallacy of the Wassermann reaction is that when it ceases to be positive in the secondary stage it does not signify that the syphilis is cured, but only that the spirochætæ pallidæ have retired from the blood into the tissues from which at some future time they may emerge and give rise to fresh symptoms. Neither mercury nor salvarsan has been proved to *cure* syphilis, though they both have a marvellous power in removing the manifestations of syphilis.

Is it certain that these long courses of mercury do not render the tissues more vulnerable rather than less vulnerable to a future state of activity of the spirochætæ? The late Sir Samuel Wilks used to say: "Mercury is a foe to syphilis, but a friend to tertiary ulceration." Would it not be well to return to the old plan of giving mercury (and for the future salvarsan) only for the purpose of removing actual manifestations of syphilis, and not with a view to preventing subsequent manifestations? With reference to the treatment of a gumma I am uncertain whether the English surgeons have given a sufficient trial to the large doses of iodide of potassium which many years ago were used with such good effect in Scotland—namely, to begin with 20 grains of iodide of potassium in a tumblerful of water on an empty stomach three times a day, and to rapidly increase the dose to 30 and 40 grains ter die, and gradually to 60 and 80 grains or more ter die, until the gumma has quite disappeared.

I am, Sir, yours faithfully,

ROBERT S. WAINEWRIGHT, M.D. Lond.

Hove, Oct. 9th, 1913.

[2] THE LANCET, 1876, vol. i., p. 536.

CLAIMS AND CONSULTATIONS.

To the Editor of THE LANCET.

SIR,—When a claim is being made in a case where personal injuries result from an accident one of the first steps taken is to have a medical examination of the injured party carried out on behalf of the person or persons from whom compensation is sought, usually an insurance company.

In common law and employer's liability—in fact, in all cases except under the Workmen's Compensation Act—the question arises as to the payment of the usual fee for the consultation between the medical examiner and the patient's doctor. It is interesting to note that in the correspondence between the parties the legal profession invariably calls for the usual fee to be paid to the patient's doctor for being present at the examination, whilst the two medical men concerned will correspond and probably arrange for a consultation to take place.

The legality of demanding a fee for allowing a claimant to be inspected or examined will not be entered into (it may be accepted much in the same light as fees paid for "discovery of documents," &c.). The fee is not always demanded, and in some cases it is arranged that the fee will be included with the other medical charges, in the "costs of the action." Medical examiners for insurance companies know only too well how great a farce some of these "consultations" become in cases where the injuries may be trivial or *nil*, where out-and-out malingerers are being dealt with, or where a denial of liability is made on sufficiently substantial grounds.

Examinations which take place in hospital are in themselves satisfactory for the simple reason that trivial cases or malingerers are not usually found in the wards of a hospital, and the records, charts, and radiographs which are usually produced constitute the essential elements of a genuine consultation. Whilst I have occasionally been present at examinations, acting on behalf of the injured party, and have received the usual fee for doing so, I am of opinion that in all cases the fee should be included with the other medical charges in the costs of the action. When a claim is made under a personal accident policy or the Workmen's Compensation Act, any fee that is paid to the claimant's doctor for being present at an examination is done so at the expense of the patient only.—I am, Sir, yours faithfully,

Castle-court, E.C., Oct. 13th, 1913. J. J. SCANLAN.

THE NATIONAL INSURANCE ACT AND MEDICAL REFEREES.

To the Editor of THE LANCET.

SIR,—I should be delighted to defer to Dr. Robert Saundby, and it would save me and other medical examiners much time and trouble if the interests of medical examiners alone had to be taken into consideration and the interests of other medical men ignored. As it is, medical examiners cannot consider only themselves, and any medical examiner who wilfully examines the patient of another medical man without his consent cannot expect to be met in consultation by that medical man on some future occasion, when it is highly necessary to obtain a medical history of a case.

In the 20 years during which I have constantly examined in London it has always been recognised that a medical examiner, when knowing the name of a private medical attendant, should, as a matter of courtesy, notify him that a medical examination is desired, and that the examiner will be pleased to meet the medical attendant in consultation. In common law, third party, and employers liability cases, there is no statutory right to demand an examination, and the claimant is not obliged to submit himself to examination; therefore either he, or his solicitor for him, usually refuses an examination except in the presence of the medical attendant and on payment of the usual consultation fee of a guinea.

Under the Workmen's Compensation Act the workman is obliged by statute to submit himself to examination by a "medical practitioner provided and paid by the employer," and therefore employers and insurance offices usually decline to pay a consultation fee. As a rule, medical men do not care to attend a consultation without a fee, and while they

therefore consent to the examiner examining alone, they resent greatly a patient of theirs being examined without the courtesy of a notification that an examination is desired. In the case of the National Insurance Act there is no statutory obligation on an insured person to submit to examination by a medical referee, and panel doctors will no doubt bitterly object to their patients being visited and examined surreptitiously, when their own treatment or certificate is also to be reported on by the medical referee. After this explanation I feel sure that the medical profession will agree with the statement made by me in the letter which appeared in your issue of Oct. 11th, for if the profession is to be united and to retain its self-respect it must be governed by ethical rules designed not for one class, but for the members of the profession as a whole.

With regard to the proposal alluded to in my letter of Oct. 11th—namely, that one body of medical referees might be appointed jointly by the Home Secretary and the Insurance Commissioners for the purposes of both the Workmen's Compensation Act and the National Insurance Act—there are many points worthy of consideration, among which are the following:—

To many leading medical men the plan has attractions, as the status of the medical referee would be enhanced, and thus better men would be available—men whose decisions would be accepted on all sides, even if "final and conclusive" with no right of appeal. In some quarters there is an agitation for a right of appeal from the decisions of the present medical referees under the Workmen's Compensation Act, and some of the arguments are weighty; on the other hand, if the medical referees were of the first rank in the profession and were in a position to command the confidence not only of their *confrères* but of the whole country, a "final and conclusive" decision would save an immense amount of delay, with worry and work to officials and any amount of clerical labour involving large attendant expense. An attractive scale of fees for such medical referees would entail but a fraction of the cost of any Apellate scheme.

It is in the interest of the Home Office, with a view not only to safeguarding the interests of employers and workmen but to enhancing the smooth working and success of the Workmen's Compensation Act, to obtain medical referees of the first class; but this Act is primarily concerned with the effects of personal injury sustained through accident, cases which require especially the expert knowledge of surgeons, and except in the case of industrial diseases the services of expert physicians are not required. On the other hand, while the Insurance Commissioners must be equally desirous of obtaining first-class medical referees, the Commission is primarily concerned with claimants alleging disease who must be examined by expert physicians if their reports are to be accepted as authoritative. There will, however, be many claims for incapacity arising from accidents occurring outside the course of employment, and therefore outside the scope of the Workmen's Compensation Act.

Now the question will naturally arise: if one body of medical referees is to be appointed under both the Acts, how can they be obtained and selected so that the profession and the public shall have confidence in them, and also how can vacancies in their ranks be filled up and a general supervision be exercised over them so that reference to a medical referee shall be followed by a prompt examination and award? Many of the present medical referees would be willing and able to accept the extended duties and responsibilities which would devolve on the new medical referees; others might probably not feel equal to the extended responsibility. In any case, a very much larger number of medical referees would be required under a conjoint scheme than there are at present. I would suggest, therefore, the formation of a small medical board of men having an intimate knowledge of the profession and its various grades. The duty of this board would be to select physicians and surgeons (preferably from local hospital staffs having the confidence of the profession in their neighbourhood), their names to be submitted to the Home Secretary and to the Insurance Commissioners, so that if approved they might be appointed as medical referees under both Acts, with full powers as to being able to give "final and conclusive" decisions, medical cases being sent for reference to physicians and surgical cases to surgeons. Under the Workmen's Compensation Act the present procedure would continue, the medical referees being notified to examine by the county court registrars as at present, the reports returned to be placed before the county court judge. Under the National Insurance Act new machinery would have to be devised if it were found impossible to use the present county court procedure. No doubt a very large expense would be saved if on application by a Local Insurance Committee, Approved Society, or panel doctor a registrar could use the present printed forms of reference to a medical referee, his report to be returned to the court and an award made by the judge. This would have much greater weight and save a great deal of trouble to the Commission.

The medical board advising both the Home Office and the Insurance Commission might receive in the first instance all complaints relating to medical matters from panel doctors, Local Committees, Approved Societies, Insurance Offices, employers, and workmen. The board might also consider all medical questions which arose, and, in fact, constitute an intelligence bureau available on all medical matters to both the Home Office and the Insurance Commission.

The working of the Workmen's Compensation Act and the National Insurance Act must be of the greatest moment to every member of the profession, and I urge medical men to consider the above points and to use their influence so that an efficient service of medical referees may be secured in the interests of the whole community.

I am, Sir, yours faithfully,

South Hampstead, N.W., Oct. 20th, 1913. ALBERT BENTHALL.

NATIONAL INSURANCE ACT: THE DIFFICULTY OF CERTIFICATES.

To the Editor of THE LANCET.

SIR,—I am glad to see that attention has been drawn by Dr. W. W. Hardwicke to the revised form of medical certificate as suggested by the Commissioners. The wording is very objectionable, and I unhesitatingly say that it will be impossible to carry on country practice unless we are allowed, occasionally at least, to delete the words: "I have to-day examined you." The only alternative would be to sign a false certificate. I have had occasion to-day to erase these words in order to enable a man of about 65 with chronic heart trouble to receive his weekly payment. The present form of certificate used by the Prudential Company is infinitely preferable to that suggested by the Commissioners. It reads: "I certify that the above-named member is still incapable of work owing to ——." So also is that used by the Rational Society: "I hereby certify that —— is in my opinion still incapable of work." We ought to insist upon the universal adoption of a similar certificate. I view with the greatest alarm the daily increase of red tape and officialism coupled with the continued somnolence of the panel doctor.—I am, Sir, yours faithfully,

T. CUMING ASKIN, M.D. Dub.

Alderton, Woodbridge, Suffolk, Oct. 20th, 1913.

THE CASE OF MR. H. T. HAMILTON.

To the Editor of THE LANCET.

SIR,—The committee of the fund to which I referred in my letter of Oct. 4th has now received the following donations:—

	£	s.	d.		£	s.	d.
F. M. G.	10	0	0	Mrs. McIntosh	5	0	0
Mr. H. Somerville	0	5	0	Mr. C. Capper...	2	0	0
Mr. J. W. Heekes	1	1	0	Dr. Cecil Johnson... ...	2	2	0
Mr. Peter Daniel	5	0	0	Dr. D. C. Dobell	2	2	0
Mr. C. N. Poole	1	0	0	Dr. W. H. Gimblett ...	2	2	0
Mrs. Moran	5	5	0				

The committee would be pleased to receive further contributions. The honorary treasurer of the fund is Mr. H. Moran, Mill Hill House, Barnes.

I am, Sir, yours faithfully,

W. H. GIMBLETT, M.D. Durh.

86, Sutherland-avenue, Maida Vale, W., Oct. 21st, 1913.

THE EXAMINATION IN ANATOMY FOR THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—I think that all who take a real interest in the welfare of the teaching of anatomy and the maintenance of a right standard of knowledge of that subject will view with regret the action of the Council of the Royal College of Surgeons of England in selecting only one of the four examiners in anatomy for the Fellowship from the ranks of the professed anatomists.

The Fellowship examination provides the one great incentive that exists in this country to induce our graduates seriously to continue the study of anatomy beyond a mere qualification standard; but if the teachers of the subject in England are to have no voice in the examination it is quite certain that such a policy will exercise a disastrous influence and react upon the methods of teaching.

At the present time strenuous efforts are being made in several schools to reform the methods and scope of instruction in anatomy, by cutting out masses of useless detail, by bringing the exposition of the significance of structure into closer relationship with considerations of function and clinical experience, and by making it a live subject rather than a mere study of dead bodies. Unless those who are actually engaged in these reforms have the only possible means of enforcing them their efforts are likely to be nugatory. It is especially discouraging that the Royal College of Surgeons should be the body to hinder such efforts. For the College is the custodian of the greatest anatomical museum in existence; and since Professor Keith became their conservator the treasures of this great collection have been elucidated in a series of brilliant and suggestive lectures and demonstrations, which have emphasised the clinical importance and value of scientific anatomy.

It has always been a matter of surprise to me that so few of the London students avail themselves of this great opportunity of acquiring useful and stimulating knowledge. I think one of the chief reasons is to be found in the nature of the College's own Fellowship examination in anatomy, which should encourage the scientific study of the human body and stimulate candidates to explore the treasures of its great collection. Instead of that, by appointing as examiners surgeons whose energies are necessarily devoted to work other than mere anatomy, the College is driving students to the crammer and the text-book monger, and paralysing the work of those teachers who are endeavouring to instruct their advanced students in a knowledge of the whole structure of the human body and its real significance.

I am, Sir, yours faithfully,

G. ELLIOT SMITH.

The University of Manchester, Oct. 21st, 1913.

THE DANGERS OF THE STREET.

To the Editor of THE LANCET.

SIR,—On a recent evening a taxicab proceeding along Piccadilly, owing to an effort made by its driver to avoid another vehicle which he found suddenly in his way, mounted the pavement and ran into the railings outside a shop. As a result the four occupants of the cab were sufficiently injured to be taken to St. George's Hospital, one of them having a leg broken, two passers-by were scalded and one of them knocked down as well. The last mentioned were women, and they and a boy, who managed, however, to jump clear, were nearly crushed against the railings. This accident is more or less a repetition of others of a similar character which have had fatal results. In at least two of these the vehicle which ran on to the pavement was an omnibus, and I do not recollect that in any such case any charge of negligence has been brought home to the driver. They have been to all intents and purposes unavoidable accidents, such as may happen at any time, and such as, in fact, do happen with tolerable frequency, but not always, of course, with fatal or serious results to the innocent foot passenger. The foot passenger, however, has a right to complain of any danger to which he is forced to submit by circumstances not altogether unavoidable. As matters stand, the danger of being crushed to death on the pavement is an appreciable one, and it must almost necessarily continue in an increased degree as motor-driven traffic becomes more and more universal, so that foot passengers may some day demand that special measures should be taken for their protection. They may fairly argue that if they cross a road, although they have a perfect right to do so in reasonable safety, they must be taken to accept a certain degree of risk, and that they have themselves to thank to some extent if they meet with an accident. On the pavement, however, they are on their own ground, and have a right to protest against being exposed to dangers that no possible prudence or foresight can predict or avert. The only remedy I can suggest is the gradual raising of pavements wherever it is practicable, or fencing them with raised kerbs. On the east side of the Edgware-road a little north of the Marble Arch, in the Brompton-road, and Kensington High-street perfectly safe pavements may be seen, being no doubt survivals of footwalks raised to keep those using them above the mud through which vehicles and horsemen had to plough their way. Perhaps some day they will be taken as examples to be imitated.

I am, Sir, yours faithfully,

London, W., Oct. 18th, 1913. E. A. A.

THE NATIONAL INSURANCE ACT.

THE FORFARSHIRE INSURANCE COMMITTEE AND NIGHT VISITS.

AT a recent meeting of the Forfarshire Insurance Committee draft rules for the administration of medical benefit were submitted by the medical benefit subcommittee, and a motion for their adoption was carried, but not before discussion had taken place upon a point closely affecting medical practitioners. Mr. H. Proctor considered that the rules were "unfair to the patients and too much in favour of the doctors," particularly with regard to restrictions as to the hours at which the latter might be summoned. It was pointed out thereupon that the rule apparently objected to was one which only stated that the insured person "shall not summon the practitioner to visit him between the hours of 8 P.M. and 8 A.M. except in cases of serious emergency." This did not satisfy the objector, who was of the opinion that it was left to the medical man to say whether a case was serious or not. He contended that if a medical practitioner was summoned by a patient who considered his condition serious he should go, and if he had any complaint to make against the patient for summoning him unnecessarily he should make it to the committee. The chairman expressed the opinion that the rules covered everything, and that if there were anything defective in them they could be amended later. A further discussion was then raised as to the steps to be taken by a patient complaining against his medical attendant, and attention was called to the rules dealing with the matter in the set of draft rules proposed before the committee. These were then adopted as stated. It is obviously necessary that such a rule as that above referred to should be imposed, as in its absence patients would have a right to assume that they were entitled to summon a medical man at any time of the day or night. Reference to the Administration of Medical Benefit Regulations, 1912, will show that it is fully intended by the Insurance Commissioners that night visits should be on a different footing from day visits, and the hours 8 P.M. to 8 A.M. are adopted by them to define a night visit.

CONTRACT PRACTICE IN MID-DERBYSHIRE.

Notice has been given by medical men in mid-Derbyshire under contracts with Friendly Societies and colliery field clubs to terminate their engagements so far as these affect their attendance upon wives and families of insured persons.

THE NEW DRUG TARIFF.

The Pharmaceutical Standing Committee on Insurance has submitted to Local Pharmaceutical Committees copies of a revised tariff for drugs and appliances which it is proposed shall form the basis of the new contracts between the panel chemists and Local Insurance Committees. This proposed

new tariff is now being discussed locally by the chemists, and if it is agreed upon will be submitted to the Insurance Committees. The principle upon which the tariff is based is not altered and is the same as that adopted in Germany—namely, a charge is made for each ingredient of a medicine according to its quantity and value plus a dispensing fee. A number of alterations in prices has been necessitated by fluctuations in the primary markets for drugs and chemicals, and prices for various quantities have in the new tariff been carried out in greater detail. Many additions have been made to the list of drugs and preparations, and these will facilitate the work entailed in making out the accounts.

Medical News.

UNIVERSITY OF GLASGOW: THIRD AND FOURTH EXAMINATIONS.—The following have passed in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health) the Third Professional Examination (Old and New Ordinance) and Fourth Professional Examination (New Ordinance) for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.):—

George Kirkwood Allan (M.), James Mair Anderson (M.), John Anderson (P.), Andrew Duffield Blakely (M.), William Ernest Boyd, M.A. (M.), John Buchanan (M.), William Edmund Alexander Buchanan (M.), John Cameron (P., M.), James Campbell (P., M.), John Munro Campbell (P.), Alfred Mackenzie Clark (P.), Allan La Barte Clark (P., M.), Robert Clark, M.A. (M.), William Cullen (P.), Fritz Vivian Daeblitz (P.), Thomas Ferguson (P.), Harry Taylor Findlay (P.), George John Fraser (P., M.), Ian Maclean Frazer (P., M.), Walter Weir Galbraith (M.), Thomas Gilchrist, M.A. (M.), George Gordon (M.), Ronald Thomson Grant (P.), Robert Milne Lang (P.), William Joseph Brown Lavery (P.), Hugh Douglas M'Crossan (P.), Archibald Munn M'Cutcheon (P., M.), Duncan Fraser Macdonald (P.), John Bowes M'Dougall (P., M.), Donald M'Donald M'Intyre (M.), Malcolm Bonar Macleod (P.), Frederick William M'Millan (P., M.), James Kennedy Manson (M.), James M'Donald Matheson (M.), John Park Mathie (M.), Thomas Spence Meighan (M.), Prem Nath (M.), John M'Lean Pinkerton, B.Sc. (M.), John Stuart Prentice (P., M.), William Burns Primrose (P.), Hugh Quigley (M.), Thomas Forbes Brown Reid (M.), George William Ronaldson (M.), Alexander Forbes Ross (M.), Archibald M'Kerrow Russell (M.), Seymour Cochrane Shanks (P.), John Sillars (M.), John Smith, M.A. (M.), Norman M'Gaan Smith (M.), John Banks Steven (M.), John Fraser Steven, M.A. (P.), Robert Sutherland Strachan (P.), Cecil Raymond Tytler Thompson (P., M.), William Thomson, M.A. (M.), James Walker (P., M.), James Gordon Wilson (P., M.), and Alexander Young (M.).

Women.—Agnes Elizabeth Mary Cooke (M.), Dagmar Florence Curjel (M.), Ethel Winifred Gompertz (M.), Margaret Walker (P.), Marguerite Wilson (M.), and Isabella Henrietta Younger (P.).

The following have satisfied the Examiners in the fourth (final) professional examination for the degrees of M.B. and Ch.B.:—

Douglas Kinchin Adams, M.A., B.Sc., Nora Maud Aden Allan, Emile Augustine Cameron Beard, Simon Harry Bloom, William Adam Brechin, David Peebles Brown, Margaret Jarvey Brown, Benjamin Cohen, Wallace MacCallum Conley, M.A., Nathaniel Crichlow, Lawrence Crombie, Daniel Augustine Cush, Gabriel Daniel de Kock, Joseph Dunbar, William Campbell Fleischmann, William Forsyth, William Fotheringham, Ian Dingwall Grant, John Galloway Hendry, William John Henry, George Hislop, Mary Pringle Hislop, William Hornsby, Alexander Lindsay, Douglas M'Alpine, James Learmont M'Bean, John Aloysius M'Connochie, L.A.H. Dub., James Walter M'Donald, John MacInnes, Annie Rankine M'Kail, Donald Mackinnon, James Robertson Cowper Mackintosh, Robert M'Lean, Andrew Paton Martin, Osborne Henry Mavor, Archibald Underwood Millar, M.A., Michael Murphy, Archibald Naismith, Thomas Murray Newton, James Purdie, Angus M'Innes Ramsay, David Smith, William Robertson Snodgrass, M.A., B.Sc., William Rowland Taylor, Carel Johannes van Lingen, Robert Bruce Wallace, and Matthew White, M.A.

At the recent professional examinations for the degrees of M.B., Ch.B., the following candidates passed with distinction in the subjects indicated:—

First Examination.—In Botany and in Physics—Robert Aitken and James Rögnvald Learmouth. In Botany—William Adams, Robert Stevenson Caldwell, James Biggam, Douglas Galbraith, Andrew Brown Macaulay Lang, M.A., John Marshall, and John Stirling Young. In Physics—William John Ferguson, Grace Leisk Hunter, Albert Ernest Lillicrap, James Robertson, and Jack Mylles. In Chemistry—William M'William and Norman Bligh Peacock.

Second Examination.—In Anatomy and in Physiology—John Dunbar. In Anatomy—Helen Young Murdoch. In Physiology—Stuart Ernest Armstrong Buckley, Maud Christine Cairney, David Campbell, M.A., B.Sc., David Clyde, Arthur Kennedy, M.A., James MacAlister Mackintosh, M.A., Alexander Fisher M'Millan, and Jane Stalker. In Materia Medica and Therapeutics—John Manteville Macfie, John King Rennie, and Andrew Stenhouse.

Third Examination.—In Pathology—Ronald Thomson Grant and John Bowes M'Dougall. In Medical Jurisprudence and Public Health—Archibald Munn M'Cutcheon.

Fourth Examination.—In Surgery and Clinical Surgery, in Practice of Medicine and Clinical Medicine, and in Midwifery—Douglas Kinchin Adams, M.A., B.Sc. In Practice of Medicine and Clinical Medicine and in Midwifery—Douglas M'Alpine. In Surgery—Carel Johannes van Lingen and Matthew White, M.A. In Midwifery—Wallace MacCallum Conley, M.A., William John Henry, George Hislop, William Hornsby, John MacInnes, and Robert M'Lean.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Eugen Ludwig, of Leipsic Anatomical Institute, has been appointed Prosector in the University Normal Anatomical Institute.—*Berlin:* Dr. Loeffler, professor of Hygiene in the University of Greifswald, has been appointed Director of the Institute of Infectious Diseases, in succession to Dr. Gaffky, who is leaving Berlin with the intention of living in retirement in Hanover, his birthplace. Dr. Kurt Strauch, *privat-docent* of Forensic Medicine, and Dr. Hermann Beyer, *privat-docent* of Otology and Laryngology, have been granted the title of Professor.—*Bologna:* Dr. Guido Vernoni has been recognised as *privat-docent* of General Pathology.—*Bonn:* Dr. Brink has been appointed Chief Surgeon to the Brothers of Charity Hospital, in succession to the late Dr. Rieder Pasha.—*Breslau:* Dr. Oskar Bondy and Dr. Fritz Heimann have been recognised as *privat-docenten* of Midwifery and Gynæcology.—*Cagliari:* Dr. Antonio Murgia has been recognised as *privat-docent* of Forensic Medicine.—*Chicago (University of Illinois):* Dr. Edgar D. Coolidge has been appointed Professor of Materia Medica, in succession to Dr. G. F. Butler, resigned.—*Gratz:* Dr. Hans Rable, professor in Innsbruck, has been appointed to the chair of Histology and Embryology. Dr. Fritz Pregel, of Innsbruck, has been offered the chair of Medical Chemistry.—*Königsberg:* Dr. Martin Kirschner, *privat-docent*, has been appointed Oberarzt of the University Surgical Clinic, in succession to Dr. Rudolf Haecker (who is going to Essen), and granted the title of Professor.—*Prague (German University):* Dr. Joseph Rambousek, a well-known authority on trade hygiene, has been granted the title of Extraordinary Professor. Dr. O. Adler has been recognised as *privat-docent* of Medicine.—*Prague (Bohemian University):* Dr. Ottoka Kutvirt, *privat-docent*, has been appointed Extraordinary Professor of Otology, Rhinology, and Laryngology. Dr. Karl Vymola, *privat-docent* of oto-laryngology, and Dr. Josef Znajemsky, *privat-docent* of surgery, have been granted the title of Extraordinary Professor.—*San Francisco (Leland Stanford University):* Dr. Leonard W. Ely, of Denver, has been appointed Adjunct Professor of Orthopædic Surgery.—*Vienna:* Dr. Robert Bárány, *privat-docent* of Otology, has been awarded the Erb medal of the German Neurological Society for his researches on the physiology and pathology of the sense of hearing.—*Würzburg:* Dr. L. Burkhardt, extraordinary professor of surgery and surgeon to the Nürnberg Hospital, is retiring.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the above society was held on Oct. 8th, Sir Thomas Boor Crosby, the President, being in the chair. Twenty members of the court were present. Three new members were elected to the society. The sum of £523 was voted to be distributed among the widows and orphans at Christmas, each widow to receive £10, each orphan £3, and each orphan on the Copeland Fund £10. It was resolved that the income from the Brickwell legacy be utilised as follows:—

1. That the legacy received from the late Mr. James Brickwell be known as the Brickwell Fund, and any grant made from it be marked as coming from that fund.
2. That the grants to widows over the age of 65 may be increased by £25 per annum.
2a. That the grants to widows under the age of 65 may be increased by £10 per annum.
3. That the grants under the Copeland Fund may be increased from the Brickwell Fund by £20 per annum.
4. That an increased grant of £15 per annum may be made to the orphans other than those in receipt of grants under the Copeland Fund.
5. That the residue of income be kept on deposit and utilised as directed by the court of directors.

The total amount of the Brickwell legacy is £37,250, yielding an annual income of £1325 10*s.* The invested funds of the society now stand at £139,500. Relief is only granted to the widows and orphans of deceased members. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20 mile radius of Charing Cross. The annual subscription is 2 guineas. Special terms for life membership. Further particulars and

application forms for membership may be obtained from the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, W.

Dr. A. K. Chalmers, medical officer of health of Glasgow, has been elected President of the Society of Medical Officers of Health for the ensuing year.

BORIC ACID IN SAUSAGES.—At Devonport recently a local tradesman was fined £2 and costs for selling sausages containing 112 grains of boric acid to the pound.

ROYAL SANITARY INSTITUTE.—The Right Hon. Earl Derby, G.C.V.O., has accepted the office of President of the twenty-ninth congress of the Royal Sanitary Institute, to be held at Blackpool from July 6th to 11th, 1914.

DONATIONS AND BEQUESTS.—By the will of Colonel John Hill, R.E., of Royal-crescent, Brighton, the Middlesex Hospital will receive £22,000.—University College Hospital, London, has received 100 guineas from an anonymous donor.

Sir M. M. Bhownaggree has presented to the London School of Tropical Medicine a medal, to be competed for annually, in memory of the late Dr. Cawas Lalcaca, who was shot on July 1st, 1909, by the murderer of Sir Curzon Wyllie.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—An address will be delivered in the college by Sir Gilbert Parker, LL.D., M.P., on Thursday, Oct. 30th, at 5 P.M. Sir Alfred Pearce Gould, K.C.V.O., dean of the Medical Faculty, University of London, will take the chair. The public are invited to attend.

CENTENARIANS.—The death occurred at Bridgwater on Oct. 13th of James Creedy, who celebrated his 100th birthday in March, 1911. He retained his faculties until near his death, and remembered the rejoicing in the town following the battle of Waterloo.—Susannah Harris, who died lately at Shipley, a village near Wolverhampton, at the age of 101 years, was born at Inkberrow, Worcestershire, on July 12th, 1812.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

FARNFIELD, W. W., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Gillingham District of the county of Dorset.

FRASER, Sir THOMAS, M.D. Edin., F.R.C.P. Edin., has been appointed Chairman of the Medical Lecturers in the Royal Infirmary, Edinburgh.

GARRETT, P. C., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Dursley District of the county of Gloucester.

LYLE, JAMES DUNCAN, M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Anæsthetist to the London Hospital.

MACEWEN, WILLIAM, M.B., M.Ch. Glasg., has been appointed School Medical Officer to the Fife and Kinross Education Committee.

MACKIE, WILLIAM, M.D., M.S. Aberd., has been appointed a Medical Referee under the Workmen's Compensation Act, 1906, for the Sheriffdom of Inverness, Elgin, and Nairn.

MAYNE, W. J. F., M.B., M.Ch. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Banbridge District of the county of Down.

NELSON, H. RUNDLE, B.S., M.D. Dub., has been appointed Quarantine Officer at William Head, Vancouver Island.

NICHOLLS, JOHN MICHAEL, L.R.C.P. Lond., M.R.C.S., has been appointed Chairman of the Cornwall Midwives Committee.

NOALL, WILLIAM PAYNTER, M.S., M.B. Lond., F.R.C.S. Eng., has been appointed Surgeon (with charge of Out-patients) to the York County Hospital.

PALMER, S., M.D. Durh., has been appointed Police Surgeon to the South District of Liverpool.

RUSSELL, WILLIAM, M.D. Edin., F.R.C.P. Edin., has been appointed to the new Moncrieff Arnott Chair of Clinical Medicine in the University of Edinburgh.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARGYLE AND BUTE ASYLUM, Lochgilphead.—Assistant Medical Officer, unmarried. Salary £175 per annum, with apartments, board, and laundry.

BIRMINGHAM CITY FEVER HOSPITAL, Little Bromwich.—Assistant Medical Officer. Salary £150 per annum, with board and residence.

BIRMINGHAM MATERNITY HOSPITAL.—Honorary Obstetric Registrar.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Two House Surgeons for six months. Salary £75 per annum, with board, residence, and laundry. Also Pathologist. Salary £50 per annum.

BRADFORD CHILDREN'S HOSPITAL.—Female House Surgeon. Salary £80 per annum.

BRADFORD UNION, EASTBY SANATORIUM.—Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with rations, apartments, and laundry.

BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—Assistant Pathologist. Salary £100 per annum, with board, residence, and laundry.

BRIGHTON THROAT AND EAR HOSPITAL, Church-street, Queen's-road.—Non-resident House Surgeon for six months. Salary at rate of £100 per annum.

BRISTOL ROYAL INFIRMARY.—House Surgeon for six months for Throat, Nose, and Ear. Salary £75 per annum, with board, apartments, and laundry.

BROMSGROVE, WORCESTERSHIRE COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £225 per annum, with quarters, board, washing, and attendance.

CARDIFF, KING EDWARD VII.'s HOSPITAL.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

CARDIFF, KING EDWARD VII. WELSH NATIONAL MEMORIAL ASSOCIATION.—Tuberculosis Physicians. Salary £450 per annum.

CARMARTHEN, JOINT COUNTIES ASYLUM.—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, &c.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—Resident House Surgeon. Salary £50 per annum, with board and residence. Also Registrars.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £100 per annum, with board, lodging, and washing.

CITY OF WESTMINSTER UNION INFIRMARY, Colindale-avenue, Hendon, N.W.—Assistant Medical Officer. Salary £160 per annum, with board, residence, and washing.

COLOMBO, Ceylon.—Assistant Medical Officer of Health. Salary £333 per annum.

DURHAM COUNTY ASYLUM, Winterton, Ferryhill.—Third and Fourth Assistant Medical Officers, unmarried. Salary £200 per annum, with board, lodging, and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Assistant Surgeon to Out-patients.

EAST SUSSEX COUNTY COUNCIL EDUCATION COMMITTEE.—Junior Assistant School Medical Officer. Salary £250 per annum.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £104 per annum.

ESSEX EDUCATION COMMITTEE.—School Medical Inspector. Salary £250 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing. Also Physician in Charge of Skin Department.

GATESHEAD ASYLUM, Stannington, Northumberland.—Assistant Medical Officer, unmarried. Salary £180 per annum, with rooms, board, and laundry.

GLASGOW UNIVERSITY.—Additional Examinerships.

GOVAN DISTRICT ASYLUM, Crookston, near Paisley.—First and Second Assistant Medical Officers. Salaries, with rooms, board, attendance, and laundry.

HASTINGS, EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary at rate of £70 per annum, with residence, board, and washing.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing.

HOLBORN UNION INFIRMARY, Upper Holloway, N.—Second Assistant Medical Officer. Salary £110 per annum, with board, apartments, and washing.

HULL ROYAL INFIRMARY.—Casualty House Surgeon for six months. Salary at rate of £80 per annum, with board and lodging.

KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, apartments, laundry, &c.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.

LEYTON, WALTHAMSTOW, AND WANSTEAD CHILDREN'S AND GENERAL HOSPITAL.—Resident House Surgeon. Salary at rate of £100 per annum, with rooms, board, and washing.

LIVERPOOL, PARKHILL HOSPITAL AND SANATORIUM FOR TUBERCULOSIS.—Assistant Resident Medical Officer, unmarried. Salary £140 per annum, with board, washing, and lodging.

LONDON COUNTY ASYLUM, Hanwell, W.—Junior Assistant Medical Officer, unmarried. Salary £200 per annum, with board, apartments, and washing.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—Three Registrars.

MACCLESFIELD GENERAL INFIRMARY.—Senior House Surgeon and Junior House Surgeon. Salary £100 and £80 per annum respectively, with board and residence.

MAIDSTONE, KENT COUNTY ASYLUM.—Fourth Assistant Medical Officer, unmarried. Salary £200 per annum, with quarters, attendance, coals, washing, &c.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Parkplace, Cheetham Hill-road.—Junior House Surgeon. Salary £100 per annum, with apartments and board.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Lecturer in Surgery.

NORTHAMPTON COUNTY ASYLUM, Berry Wood, Northamptom.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

NORTHAMPTONSHIRE COUNTY COUNCIL EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £250 per annum.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100 per annum, with board, residence, and laundry.

OXFORD COUNTY ASYLUM, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing.

PADDINGTON INFIRMARY.—Second Assistant to Infirmary and Medical Officer of Workhouse. Salary at rate of £100 per annum, with board, lodging, and washing.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, residence, and washing. Also House Surgeon. Salary £100 per annum, with board, residence, and washing.

PORTSMOUTH ROYAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, &c.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Assistant Gynæcologist.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer for Out-patient Department for four months. Salary at rate of £60 per annum, with board, residence, and washing.

READING, ROYAL BERKSHIRE HOSPITAL.—Surgical Registrar.

RICHMOND, SURREY, ROYAL HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board, apartments, and washing.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Assistant Physician. Also House Surgeon for six months. Board, lodging, and washing provided.

ST. GILES, CAMBERWELL, INFIRMARY, Brunswick-square, Camberwell.—Junior Assistant Medical Officer. Salary £120 per annum, with apartments, board, and washing.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Junior Resident Medical Officer for seven months. Salary at rate of £70 per annum, with residence, board, and laundry.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Senior House Surgeon. Salary £100 per annum, with board, residence, &c.

SHEFFIELD ROYAL INFIRMARY.—Surgical Registrar. Salary £100 per annum.

SOUTH LONDON HOSPITAL FOR WOMEN.—Three Clinical Assistants.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Demonstrator in the Department of Bacteriology. Salary £150 per annum.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Surgeon to In-patients and Surgeon to Out-patients.

VIRGINIA WATER, SURREY, HOLLOWAY SANATORIUM HOSPITAL FOR THE INSANE.—Junior Assistant Medical Officer. Salary £250 per annum, with board, lodging, laundry, and attendance.

WARRINGTON, LANCASHIRE COUNTY ASYLUM, Winwick.—Assistant Medical Officer, unmarried. Salary £200 per annum, with board, apartments, attendance, and washing.

WEST BROMWICH AND DISTRICT HOSPITAL.—Assistant Resident House Surgeon and Anæsthetist, unmarried. Salary £75 per annum, with board, residence, and washing.

WESTERN OPHTHALMIC HOSPITAL, Marylebone-road, W.—House Surgeon. Salary £100 per annum.

WEST LONDON HOSPITAL, W.—Assistant Dental Surgeon. Also Second X Ray Officer.

WHITECHAPEL UNION INFIRMARY, Vallance-road, E.—Second Assistant Resident Medical Officer. Salary £120 per annum, with rations, apartments, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £140 per annum, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Acts at Stoney Stanton, in the county of Leicester.

Births, Marriages, and Deaths.

MARRIAGES.

ADAMS—WEBB.—On Oct. 14th, at St. Nicholas' Church, Chislehurst, by the Rev. J. E. Dawson, rector of Chislehurst, assisted by the Rev. C. F. Kite, vicar of North Petherwyn, and the Rev. F. W. Ainley, vicar of St. Andrew's, Barnsbury, Joseph E. Adams, M.S., F.R.C.S., of 40, Devonshire-place, W., to Muriel, youngest daughter of the late Harry Webb and Mrs. Webb, of Southlaund, Chislehurst.

EDWARDS—STANTON.—On Oct. 15th, at Christ Church, Cheltenham, Hugh Anderson Edwards, M.B., Ch.B., Wallsend-on-Tyne, to Illma Irene Stanton, youngest daughter of the late Alfred Alexander Stanton, of Johannesburg.

HOLLAND—COLGATE.—On Oct. 17th, at the Parish Church, Eastbourne, by the Rev. Wm. C. Streatfeild, Eardley Lancelot, eldest son of W. Lancelot Holland, M.A., of Worthing, to Dorothy Marian, elder daughter of Dr. Henry Colgate and Mrs. Colgate, of the Seven Gables, Eastbourne.

PAINTON—EVEN.—On Oct. 15th, at the Church of St. Mary-at-the Walls, Colchester, Captain George R. Painton, R.A.M.C., to Aileen Mona, daughter of Colonel G. E. Even, C.B. (Indian Army), and Mrs. Even, of Inglis-road, Colchester.

DEATHS.

ADAM.—On Oct. 19th, at Dingwall, Ross-shire, Scotland, suddenly, John Adam, M.D.

ANGUS.—On Oct. 18th, at Thornleigh, Bentinck-road, Newcastle-on-Tyne, suddenly, James Acworth Angus, M.R.C.S., L.S.A., in his 78th year.

CARPENTER.—On Oct. 15th, at Croydon, Arthur Bristowe Carpenter, M.A., M.B. Oxon., M.R.C.S., L.R.C.P., aged 59 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE NEW NORWEGIAN PHARMACOPŒIA.

THE now published fourth edition of the Norwegian Pharmacopœia will, from Jan. 1st, 1914, take the place of the edition in force since 1895. The new work embodies many features of modern research in pharmacy and testifies to the high scientific attainments of Norwegian pharmacists. In many respects this edition resembles the German Pharmacopœia of 1910, with which it has many points in common; for instance, a list of the reagents used in the analysis of urine, blood, stomach contents, and stains for bacteriological work is, as in the latter, also included in the appendix, and a large number of the tests for purity are similar in both works.

One noticeable feature on looking through this work of 480 pages is the peculiar Latin nomenclature adopted for the titles of the articles—the text itself is throughout in Norwegian—which differs materially from the Latin forms in use in Great Britain or in other continental countries. Aqua assumes the form "aqva," potassii bromidum is rendered "brometum kalicum," and we find carbonas natricus, chloretum morphicum, liqvor arseniitis kalici, nitras argenticus, oxydum magnesicum leve. The existence of such divergent designations for one and the same substance in the classic tongue surely calls for uniformity in the nomenclature of official drugs; thus the "Latin" designations for ammonium chloride in use in various Pharmacopœias are respectively: Ammonii chloridum, ammonium chloratum, and chloretum ammonicum.

In the present edition 41 articles have been deleted and 85 substances have been added. Among the newer remedies included figure acetyl-salicylic acid, diethyl-barbituric acid, suprarenin bitartrate, creosote carbonate, hexamethylenetetramine, novocaine, silver proteinate, antipyrine salicylate. Instead of enforcing an absolute content of active principle in the galenical preparations of potent drugs, a maximum and minimum content is prescribed. Thus, extract of belladonna is required to have a content of not less than 1 or more than 1·2 per cent. of alkaloids, extract of nux vomica 15 to 17 per cent. of total alkaloids, extract of opium 18 to 20 per cent. of morphine. In the case of liquid extracts and tinctures the specific gravity as well as the percentage of residue obtained on evaporating and drying a given amount of the preparation is stated. In view of the discussions as to the relative value of freshly prepared infusions and those prepared by diluting a concentrated extract of the drug with water, it is interesting to note that the new Norwegian pharmacopœia includes concentrated infusions of condurango, ipecacuanha, senega, and valerian, prepared by percolation and standardised to represent a fixed amount of drug, and, in the absence of instructions to the contrary, directs that the prescribed amount of infusion shall be prepared from the concentrated product by diluting it with water.

An interesting requirement is prescribed in the monograph on digitalis leaves. The latter are to be dried for five hours at a temperature of 80° C., and then filled into well closed containers not holding more than 50 grammes; this requirement gains additional importance in view of recent research work on the action of the enzymes in the leaves, and their effects on the activity of the dried drug. Another innovation is found in the method now adopted of preparing bitter almond water (which on the continent is more generally employed than cherry-laurel water); the time honoured process of preparing this dilute solution of hydrocyanic acid by distillation of bitter almonds has been abandoned and a "synthetic" product substituted, prepared by mixing oil of bitter almond 4, hydrocyanic acid 50, alcohol 146, distilled water 800. Among other innovations may be noted the inclusion of the molecular weights and chemical formulas, and of the optical rotation indices of essential oils.

MEDICAL REPORT ON CYPRUS.

THE Blue-book of Cyprus for the past year includes a report by Dr. R. A. Cleveland, head of the Medical Department, in the course of which he states that the general health of the inhabitants and the sanitary conditions of the island have been satisfactory. The outbreak of small-pox in 1911 died out during 1912, only five cases occurring during the earlier months with no deaths, and the island has now been free from the disease for some time. The prevailing diseases in 1912 were malaria, diseases of the digestive and respiratory systems, eye and skin diseases. Only 24 cases of cerebro-spinal meningitis were reported during the year, and these of a mild type. Of diphtheria only three cases were recorded. The number of cases of enteric fever showed an increase, being 447, as compared with 299 reported in 1911 and 334 in 1910. The rate of mortality, however, is not high, and the disease still retains the mild type peculiar to Cyprus. There has unfortunately been a considerable increase in the number of cases of malaria treated by the Government officers of the island, as shown by the following figures: cases in 1907, 7561; 1908, 10,746; 1909, 7450; 1910, 6074; 1911, 7198; and 1912, 10,035. No serious epidemic prevailed during the year, and there was no case either of plague or cholera.

In the six district hospitals 2492 in-patients and 20,904 out-patients were treated, and at the 13 rural dispensaries 13,230 were treated. The Central Hospital at Nicosia has done valuable work, and the staff is competent and sufficient for the requirements of the institution. The maternity wards have been fairly successful, but notwithstanding their convenience and comfort, and the excellent attendance that is offered, they do not gain in popularity. At the Larnaca Government-aided hospital a ward for children has been opened, and is doing very good and useful work with a trained English nursing sister in charge of the management. Fewer cases of leprosy were admitted to the Leper Farm than in previous years. It is, perhaps, premature to express a definite opinion, but the disease seems to be decreasing in the island. So far as is known, all fresh cases are sent up as soon as the disease shows itself.

The Acting High Commissioner, in his "General Observations," remarks: "Cyprus was fortunate in obtaining at the end of the year the services of Sir Ronald Ross, K.C.B., F.R.S., to investigate malarial conditions in the island and to make recommendations as to the method of combating the disease. Spleen measurements taken at a variety of village schools showed that the disease is dangerously common in certain villages, and vigorous steps will probably have to be taken to eliminate it. Unfortunately, the Cypriote peasant is apathetic with regard to sanitation, and it is difficult to get sanitary regulations, even of the most simple kind, carried out unless a large staff of Government overseers is appointed."

The absolute mean temperature for 1912 was 65·6° F., which was nearly the same as the mean of the last ten years. The winter, though colder than that of the preceding year, was above the average, and snow only fell once on the Kyrenia hills. The lowest temperature recorded at Nicosia was 31° on Feb. 2nd and the highest 103° on Sept. 27th. Nicosia still shows a higher summer temperature than any neighbouring place, though Suez and Khartoum are both slightly higher.

THE USE OF COLOUR IN BOOKBINDINGS.

To the Editor of THE LANCET.

SIR,—I have been interested in the letter by "Bouquineur" in your issue of Oct. 4th on the use of colour in bookbindings, a differentiation that seems to meet with some measure of your support. Would it not be an easy solution of the difficulty for anyone who wishes to make such distinctions to cover his books with paper of any colour he might fancy for works on the various subjects? This would, besides, keep the bindings clean. I am, Sir, yours faithfully,

Argyll-terrace, Derby, Oct. 21st, 1913. F. J. R. CARULLA.

A VISITING WORKHOUSE SURGEON.

THE Brighton guardians at a recent meeting decided by 18 votes to 7 to appoint a consulting and operating surgeon at the workhouse for a period of one year at a payment of 100 guineas for his services. When the guardians originally suggested such an appointment the medical practitioners of the neighbourhood took such a decided objection to the salary of 50 guineas then allocated to the office that they managed to bar any applications for the appointment. The guardians, however, had gone so far as to fit up a special room and purchase the necessary instruments. The assistance of the Local Government Board was invoked, and after considerable negotiations the medical practitioners expressed themselves agreeable to the appointment at the salary of 100 guineas, and the board of guardians has now passed the necessary resolution, preferring this scheme to one for the appointment of a number of specially skilled surgeons whose services should be at the disposal of the medical officer at a prearranged scale of charges. Mr. Lowry, an inspector of the Local Government Board, who was present at the guardians' meeting when the vote was taken, said that visiting surgeons had been appointed to infirmaries in other towns for one year, and he foresaw no difficulty in obtaining the approval of the Whitehall authorities. It would, Mr. Lowry added, be a distinct advance to have a visiting surgeon a the workhouse.

REDUCED DEATH-RATES IN BAVARIA.

IN his annual report on the affairs of Bavaria Mr. A. Abbott, British Vice-Consul, writes: The mortality from tuberculosis has decreased during the last 30 years from 254 to 204 per 100,000, but the diminution has taken place exclusively during the last five years and is the result of the strong action in favour of popular sanatoriums. In the last three decades the mortality from diphtheria has sunk from 12 to 21 per 100,000, that from typhoid from 22 to 2 per 100,000, scarlet fever from 45 to 7 per 100,000, and measles 35 to 24 per 100,000. The mortality among infants in their first year is in Germany about 400,000 per annum, or 19·8 per cent. of the births. In the case of illegitimate

children, of whom nearly 180,000 are born each year, the birth-rate in the first year is 32·7 per cent. Bavaria has the highest infantile mortality of all the German States, but the figures for 1912 are more favourable, and show that only 37,013 children under one year died, as compared with 46,665 in the previous year. The rate in the cities was 15·5 per cent. of the births (in 1911 20 per cent.); in the country, 18·4 per cent. (22·9 per cent. in 1911). The high figures for 1911 are, however, due in part to the hot summer. The rate in Munich has sunk very noticeably, the figures being; 1891-95, 30·3 per cent.; 1896-1900, 28 per cent.; 1900-5, 26·6 per cent.; and 1906-10, 19 per cent. To improve conditions the Bavarian Parliament has appropriated £2500. An association for the care of infants has been started, and will found affiliated societies in the provinces. Prominent officials and physicians are to take part in the work. The hospital treatment of infants has made great advances. Twenty years ago the infant mortality in the hospitals was from 60 to 70 per cent.; at present it is lower than the general infantile death-rate, although the hospitals only receive severe cases. A sanatorium for consumptive children is being built near the Lake of Constance at a cost of £25,000.

DRUG-TAINTED MILK IN EAST PRUSSIA.

IN a recently issued police by-law regulating the sale of milk in the province of Eastern Prussia a rule has been inserted prohibiting the sale of milk from cows undergoing treatment with potent drugs liable to pass into the milk, or from cows treated with such remedies during the last three days preceding the sale of the milk. Such remedies are particularly aloes, arsenic, arecoline, tartar emetic, veratrum, salts of mercury, iodine, eserine, pilocarpine, strychnine, and other alkaloids.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SECTION OF ODONTOLOGY (Hon. Secretaries—Robert McKay, F. Coleman): at 8 P.M.

President's Introductory Address:
Mr. C. F. Rilot.

Paper:
Mr. Stanley P. Mummery: The Conservative Treatment of the Pulp.

TUESDAY.

SECTION OF MEDICINE (Hon. Secretaries—H. Batty Shaw, John Fawcett): at 5.30 P.M.

Sir William Osler, Bt., F.R.S.: Congenital Syphilis of the Liver, with the Picture of Banti's Disease.

Dr. Poynton, Dr. Armstrong, and Dr. Nabarro: A Contribution to the Study of a Group of Cases of Chronic Recurrent Diarrhœa in Childhood.

Dr. Gossage and Dr. Braxton Hicks: Two Cases of Non-cancerous Tumour of the Stomach.

SECTION OF PSYCHIATRY (Hon. Secretaries—R. H. Cole, Bernard Hart): at 8.15 P.M.

Demonstration:
Dr. J. W. E. Cole: Case of Pellagra with Insanity.

Paper (at 8.30 P.M.):
Dr. Mercier: What is Insanity?

THURSDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawfurd, D'Arcy Power): at 5 P.M.

Professor G. Elliot Smith: The Contributions of Ancient Egypt to the History of Medicine.

The lecture is open to all members of the Medical Profession, whether Fellows of the Royal Society of Medicine or not, and to others interested in the subject.

SECTION OF NEUROLOGY (Hon. Secretaries—T. Grainger Stewart, H. Campbell Thomson): at 8.30 P.M.

Presidential Address:
Mr. William Thornburn.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on the Visceral Complications met with in Hysterectomy for Fibroids, and the Best Method of Dealing with Them (introduced by Sir John Bland-Sutton).

BRITISH OTO-LARYNGOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

WEDNESDAY.—4 P.M., Clinical Meeting.

CHILD STUDY SOCIETY, LONDON, Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY.—7.30 P.M., Prof. W. Rippmann: Child Speech.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Myxoma and Chondroma. (Museum Demonstration.)

WEDNESDAY.—5.30 P.M., Mr. Colyer: Specimens illustrating Irregularities of the Teeth in Man. (Museum Demonstration.)

FRIDAY.—5 P.M., Prof. Keith: Specimens illustrating Certain Points in the Anatomy and Physiology of the Ear. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. MacCormac: Clinique (Skin). 5.15 P.M., Lecture:—Mr. M. Yearsley: Common Errors in Diagnosis—Ear.

TUESDAY.—4 P.M., Dr. P. Parkinson: Clinique (Medical). 5.15 P.M., Lecture:—Dr. R. H. Miller: Common Errors in Diagnosis—Children.

WEDNESDAY.—4 P.M., Mr. H. Lett: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. A. H. Tubby: Common Errors in Diagnosis—Joints.

THURSDAY.—4 P.M., Mr. P. Turner: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. A. Carless: Common Errors in Diagnosis—Sprains and Fractures.

FRIDAY.—4 P.M., Sir StClair Thomson: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Ll. Williams: Caries, its Causes, Prevention, and Treatment.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Diseases of Throat, Nose, and Ear.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Mr. Ll. Williams: Diseases of the Gums and Periosteum—Causes, Prevention, and Treatment.

THURSDAY.—10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Address:—Sir Gilbert Parker, M.P.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Dr. Owen: Practical Medicine. 12.15 P.M., Lecture:—Dr. Bernstein: Clinical Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Diseases of Nose, Throat, and Ear.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.30 P.M., Special Lecture:—Dr. C. Singer: Gastric Ulcer.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. B. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery. 3.15 P.M., Special Lecture:—Mr. L. V. Cargill: Optic Neuritis.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Mr. P. P. Cole: Cancer of the Breast.

FRIDAY.—Out-patient Demonstrations;—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford; Medicine. 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. B. Bickerton: Eye.——10 A.M., Col. Barry: Radiography.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

Course of Lectures on the Neuroses and Psychoses of Children:—

TUESDAY.—2 P.M., Dr. F. Warner: Development of Mental Action.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4.30 P.M., Lecture:—Dr. Burrell: The Complications of Pulmonary Tuberculosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Mr. F. Batten: Cerebral Diplegia.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. A. Turner: Compression Paraplegia.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Mr. Hampson: X Rays. The Tube and its Control.

THURSDAY.—6 P.M., Dr. M. Dockrell: The Treatment of Eczema in all its Forms.

MANCHESTER HOSPITALS POST-GRADUATE CLINIC.

TUESDAY.—SALFORD ROYAL HOSPITAL—4.30 P.M., Dr. C. C. Heywood: Chorea.

WEDNESDAY.—ROYAL INFIRMARY—4.30 P.M., Dr. Reynolds: Some Unusual Causes of Lead Poisoning and the Remote Results.

THURSDAY.—ANCOATS HOSPITAL—4.30 P.M., Dr. Bythell: X Ray Treatment in Exophthalmic Goitre, Hodgkin's, and Carcinoma.

FRIDAY.—ROYAL EYE HOSPITAL—4.30 P.M., Dr. T. M. Bride: Detachment of Retina, Vitreous Opacities.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Abnormal Presentations of the Fœtal Head. 11 A.M., Examination of Patients and Minor Operations.

TUESDAY.—10 A.M., Major Operations.

WEDNESDAY.—10 A.M., Obstetrical Lecture: Abnormal Presentations of the Fœtal Head (continued). 11 A.M., Examination of Patients and Minor Operations.

THURSDAY.—10 A.M., Major Operations.

FRIDAY.—10 A.M., Gynæcological Lecture: Gynæcological Diagnosis. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 26th–Nov. 5th (Ghent).—International Exhibition.

May–October (Leipzig).—First International Building Exhibition.

June 24th–Oct. 31st (London, 54a, Wigmore-street).—Historical Medical Museum. (Organised by Mr. Henry S. Wellcome.)

June–October (London, Crystal Palace).—Anglo-German Exhibition.

Oct. 1st–Nov. 1st (London, Shepherd's Bush).—National Gas Exhibition.

,, 9th–25th (London, Olympia).—Ideal Home Exhibition.

,, 22nd–25th (Berlin).—Eleventh International Anti-Tuberculosis Conference.

,, 28th–Nov. 1st (London, Royal Horticultural Hall).—Twenty-fourth Universal Cookery and Food Exhibition.

Nov. 7th–15th (London, Olympia).—Twelfth International Motor Exhibition.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial Staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The Harveian Oration

ON

THE INFLUENCE OF HARVEY'S WORK IN THE DEVELOPMENT OF THE DOCTRINE OF INFECTION AND IMMUNITY.

Delivered before the Royal College of Physicians of London on Oct. 18th, 1913,

BY J. MITCHELL BRUCE, M.A., M.D., LL.D.,

FELLOW OF THE COLLEGE.

MR. PRESIDENT,—It is my privilege and duty to-day to interpret the spirit that moved Harvey when he instituted this annual feast and oration, and to convey to the Fellows and Members and others in appropriate form the message that he left us for all time.

INTRODUCTORY REMARKS.

Harvey's character is reflected in his deed of gift. His devoted attachment to the College and solicitous thought for her corporate interests in the future are seen in his direction to the orator to commemorate benefactors and exhort others to imitate them. On this occasion I cannot do so more fittingly than by reminding you of the reference that you, Sir, made a few months ago, in your eulogy on the life and character of the late Dr. Theodore Williams, to the intention that he expressed in his will to leave conditionally to the College the sum of £5000. Dr. Williams had proved his filial interest in the College in other ways during his life, and in this promised gift, which he directed to be devoted to hospitality and the maintenance of the dignity of the College, he has done more than set us an example of liberality which each of us, as far as in him lies, should strive to follow. He has approved in deed what he commended in word from this very place two years ago—the cultivation and practice of the custom of generous social entertainment within the College, that the "mutual love and affection," which it is also my duty to exhort you to continue, may not be a passing sentiment during our individual lives, but be perpetuated in the fortunes of the College itself, of which it is one of the surest guardians.

Harvey's remaining direction to the Orator reveals what lay as close to his heart as the advancement of "the society" itself. In pious conformity therewith I have now to exhort the Fellows and Members to search and study out the secrets of Nature by way of experiment. To those of our Fellows and Honorary Fellows who are pure scientists, and to that other happily considerable number of our Fellows and Members who devote part of their time to exact research, I need offer a passing salutation only—they are working on Harvey's own lines. But what, I have had to ask myself, am I to say by way of exhortation to the general body of our Fellows and Members who, leading laborious lives full of professional and other concerns, may easily lose in their routine work the opportunities and methods of scientific observation? I will exercise, yet in all humility as being myself one of their number, the privilege of the position of brief authority to which you, Sir, in your great kindness have elevated me to-day, and will offer them a word of counsel on a subject which Harvey himself selected when about to address a body of practising physicians.

HARVEY'S VIEWS ON THE CAUSATION OF DISEASE.

In the fifth Canon of his "Prelectiones," the rough notes which he prepared to serve as guides in his Lumleian lectures, Harvey gives the first place among "exotic" subjects to causes. He plans "to bring in points beyond mere anatomy in relation to the causes of diseases and the general study of Nature, with the object of correcting mistakes and of elucidating the use and action of parts; for the use of anatomy to the physician is to explain what should be done in disease." *Ob causas Morborum: Medicis praecipue utilissimas* are the opening words under the head of *observationes exoticas; et inde Quid agendum morbis* are the concluding words of this pregnant Canon; and the two expressions are linked together by two others—"the general study of Nature" (*varietatem Naturae philosophicae*) and "the structure and functions of the body" (*constitutionem naturalem*), indicating the scientific connexion of the first and last. Note that this is no casual remark of Harvey. It represents the plan of his lectures, deliberately worked out, carefully formulated, and no doubt closely followed.

Reflecting on this passage in the history of Harvey as a lecturer, I asked myself what came out of the striking declaration, "*Causas morborum medicis praecipue utilissimas*," in the course of the next 250 years. Harvey's declaration was in the possession of his successors, many of them, no doubt, his pupils; his life and methods were annually held up to their contemplation as an example to follow; and he had also left to them in his writings, as I shall presently remind you, certain profound reflections on contagion, immunity, and spontaneous recovery, and—in the same connexion—on evolution, which might well inspire them. Moreover, the question of causation, particularly in respect of fever, was before the minds of thoughtful practitioners of the seventeenth and eighteenth centuries at every moment; and we know that the "proximate cause" of fever lay at the root of the different doctrines which exercised so much the minds of learned physicians and philosophers of the time, connoting as it did the reaction of the body to morbific agents, and indirectly the problem in what life itself consists.

I concluded that, instead of using words of formal exhortation, I should best fulfil my duty of to-day by reviewing with you the history of the doctrine of the causes of fever from the death of Harvey to the present time. The development of this doctrine might be expected to prove the value of Harvey's reiterated affirmation that in the solution of the problems of medicine experiment (which, as he used the term, included "diligent observation") leads to success, whilst "empty assertions, mere suppositions, and false sophisticated reasonings" end only in error, confusion, and delay.

Let us see what contributions the physicians of those days, working in different fields and following different methods, respectively make to the knowledge of infectious diseases and the natural history of contagion within and without the body. I say "working in different fields," for there were two fields of observation and action largely independent of each other in which physicians had opportunity to unravel the theoretical and practical problems connected with the origin and nature of fever.

The first field was that of the men who practised, and in many instances spent their lives, in the very circumstances in which fever was bred and spread—in the slums of London and other cities, in connexion with jails, and in the naval and military services. They had the problem of prevention as well as that of treatment constantly before their minds, and they already deserved the name of sanitarians. The other field was that of the clinical observers in civil hospitals and in the west-end of London, away from the hotbeds of infection. Their interest in fever concerned its phenomena, and the indications to be found in them for guides to treatment, and they gave little thought to the insanitary conditions in which the disease arose.

OBSERVATIONS IN THE FIELD OF SANITATION.

I begin with the observers of fever in its breeding places. It was they who insisted on the connexion of contagion with insanitation, and traced out the social circumstances in which insanitation arises; and it was from their observations and earnest, persistent representations that public health legislation in this country took its beginnings. At the time of the death of Harvey in 1657 they were already in possession of the knowledge that epidemic diseases arise from contagion and dirt, and they had only too many occasions of confirming and applying it.

During the 150 years from the death of Harvey to the first decade of the nineteenth century the descriptions of conditions under which fevers flourished in the civil population of this country, and in the naval and military services, by competent medical observers like Mead, Lind, Pringle, and Smollett, are almost revolting. General poverty and ignorance and hand-to-mouth existence breaking down when famine happened to prevail, led to overcrowding into tenements in towns, where men, women, and children lived wretched and dissolute lives, without the smallest provision for a supply of

wholesome water, or the removal of dejecta, effluvia, and dirt of other kinds. Ventilation was at a premium, for the window tax had fallen on habitations, and also on jails and prisons maintained and worked on a corrupt proprietary system and crowded with debtors and criminals alike. The inmates of these, on their release, spread fever in town and country, or were immediately pressed into ships of the Royal Navy, which were ready to be infected because of the entire absence of means of ventilation.

Along with these miserable circumstances of the bulk of the population there prevailed during most of the eighteenth century among the governing classes of the country a lamentable indifference to other concerns than their own immediate privileges and pleasures. Even when blessed with peace abroad the country did not turn to domestic reform. Prosperity and unwonted ease begot improvidence. Drunkenness was so much the resource of the poor and the fashion of the well-to-do that in 1726 the College made a representation on "the fatal effects of the frequent use of distilled spirituous liquors" on the individual and on the race to the House of Commons, through Dr. Freind, one of its Fellows and Member for Launceston. The pens of Fielding and Smollett and the brush of Hogarth inform us of the coarse joviality, grossness and vice of the times; and we can study for ourselves in story and in picture the utterly insanitary—indeed, filthy—conditions in which the people lived, and from time to time by the thousand died. Fever and death raged discontinuously in the form of destructive epidemics throughout the whole of the eighteenth century.

The Beginnings of Preventive Medicine.

In those times of physical and social corruption the foundations were laid of preventive medicine in England, and after England in the world, by the isolated efforts of a few medical men. In 1720 Richard Mead, a Fellow of this College and physician to St. Thomas's Hospital, published his "Short Discourse concerning Pestilential Contagion and the Methods to be used to Prevent it," in response to an appeal by the Government for advice. Plague was raging in France, and must be prevented from entering England. With this object Mead recommends a strict quarantine. If it should invade the country, it must be prevented from spreading; and in this matter Mead is a genuine reformer. He condemns the system of shutting up infected houses, the sick and the healthy together, until all have either died or recovered—a system which drives people to conceal the disease at its beginning, and lets loose the survivors to spread fresh infection. He recommends the establishment of a Council of Health, with local officials to isolate infected persons, to cleanse sound persons and remove them to new lodgings. No expense is to be spared to save the nation from the greatest of calamities. Infected houses should be pulled down and their contents burned, all habitations made clean and airy, streets washed, beggars provided for in hospitals, and unnecessary assemblies prohibited. The Government of the day, thoroughly alarmed—obviously in part for their individual safety—gave effect to Mead's recommendations by Act of Parliament, but within a year, moved by faction, they repealed part of its provisions.

Thirty years later there was published a letter to Dr. Mead on the Nature and Cure of Hospital and Jayl Fevers, by John Pringle, Fellow *speciali gratiâ* of the College. In 1750 the court at the Old Bailey was infected by putrid effluvia brought by the prisoners from Newgate prison, and two judges, counsel, the Lord Mayor, and others—more than 40 persons in all—perished: the sixth Black Assize. Pringle, who had studied typhus intimately in camps and military hospitals when Physician-General to the Forces, and traced the connexion of it with putrid air, filth, damp, and other causes, including conditions of place and season, recommended a system of ventilation which was carried out. In those early days, as again a century later, Civil sanitation learned some of its best lessons from the Army Medical Service.

Work of equal value in the investigation of the causes and prevention of disease in the British navy was done at the same time and during the next 20 or 30 years by Dr. James Lind, physician to Haslar Hospital, and Dr. Gilbert Blane. Lind identified "ship fever," "jail fever," and "hospital fever" as all one disease with typhus—an advance of incalculable value in its bearing on the spread of infection. He traced not only typhus and scurvy to their respective origins in the unwholesome conditions of routine ship life, but he showed how to prevent them. Observations to the same effect were being made in the civil populations of London and other cities. This was the period of Dr. John Hunter, who in a paper to the College identifies the typhus of the West-end of London with the jail and hospital fever of his military experience, and gives a graphic description of the poverty and consequent insanitation of the people; of Samuel Johnson's Dr. Robert Levett,

> "Of every friendless name the friend,"

who laboured among the poor behind Fleet-street; of Lettsom in the City, who carried his patients out into the cold fresh air and wondered at the long neglect of the method; of Dr. John Fothergill, who recommends "free air" for the putrid sore throat, first recognised and described by him in this country; and of Willan, who as physician to the public dispensary attended the poor of the district between the Strand and Holborn and of the City, and traced the invasion and complete depopulation of some parts of it by fever to life in overcrowded and foul habitations.

Growing Influence of Common Humanity in Social Politics.

But we must be fair in our record. Another influence than medical science was at work in England in the middle of the eighteenth century—a growing influence of common humanity in social politics. It is true that it was as administrators, in their different offices and spheres of public activity, that Pringle on the battlefield, Gilbert Blane afloat and ashore, Lind at Haslar, Captain Cook in command of the *Resolution*, and John Howard on his first memorable visit to a county prison, severally started a movement which was destined to mitigate incalculable suffering, save countless lives, and elevate the masses physically and morally. But these men were gifted with noble and tender hearts as well as intelligent minds, and in that respect they appear in the history of preventive medicine as the outstanding representatives of "the large sympathy of man with man which," in the eloquent words of John Richard Green, "especially marks the eighteenth century as a turning point in the history of the human race."

But legislation does not wait at once on sentiment. By the end of the eighteenth century nothing of value was done in the way of providing a public supply of water to serve as wholesome drink and remove sewage, nor was there any provision for dealing with epidemics, although 1796 will ever be memorable as the year in which Jenner discovered the value of vaccination by strictly scientific experiments. The first visitation of cholera in 1831 found the country still entirely unprepared in respect of sanitation to prevent the spread of infection. Not even yet was there any proper drainage system; every house was built over its own cesspool. Of nuisances there was no public control.

General alarm, begotten of reports from the continent of the ravages of cholera, and of a growing acquaintance with the insanitary state in which the people were living, led to the establishment of a Board of Health, after a consultation between the Privy Council and the College, its President, Sir Henry Halford, becoming President of the Board. "Rules and Regulations" for the purpose of preventing the introduction and spreading of the disease were circulated, which related to sanitation in detail, but mostly were of no binding effect on the public; and what the condition of insanitation of most of our towns was in relatively recent times may be gathered from the record that in 1847 typhus killed over 30,000 persons in England and Wales, and typhoid fever 78,000 persons in the ten years 1871–1880.

The Success of the Economic Argument.

It is humiliating to unravel the moving force that at last set Parliament in action, and led to the public health legislation of 1848. What neither medical representations and offers of medical assistance, backed by recent advances in chemistry, physics, physiology and pathology, nor the growth of common humanity could effect, excepting in piecemeal fashion on grave occasions, was prompted and promoted by considerations of economy. The high mortality from fever had cut off in their prime thousands of bread-winners, leaving their widows and children paupers, and it had also reduced to temporary destitution those who survived. The poor rate had risen to an alarming height, and the Poor-law Commissioners, tracing this increase ultimately to public

insanitation, represented to the Government in 1838 that prevention would be more economical than mitigation. Their appeal was backed by reports from three distinguished physicians—Dr. Neil Arnott, Dr. James Philip Kay, and Dr. Southwood Smith—on the prevalence of physical causes of fever in the metropolis and the prevention of them. In these reports there is little that is new, in respect either of the description of general insanitation and misery and their fatal effects on the population, old and young, or of the principles on which public measures were recommended to correct them, as compared with Dr. Mead's "Short Discourse" drawn up 118 years earlier. The economic argument prevailed; and the appointment of a Royal Commission on the Health of Towns in 1843 was followed by various legislative steps, and finally by the Public Health Act in 1848.

From that date to the present time the machinery of public sanitation, so hard to set in motion, has undergone continuous development. Exact science was waiting to assist it—at first spontaneously, afterwards with the help of Government grants through the Privy Council or Local Government Board on the recommendation of Simon. The two agents which their predecessors had continuously associated with fevers—contagion and dirt—were being thoroughly investigated. In 1849 Snow referred the spread of cholera to the infected dejecta, and ten years later it was definitely traced to contamination of the water-supply. First one and then another medium of infection hitherto unsuspected was discovered—particularly by Greenhow's historical reports on industrial diseases, and the investigations into the connexion of scarlet fever, diphtheria and summer diarrhœa with milk, and of typhoid fever with water. In the last 50 years the progress of sanitation on scientific lines has been rapid and uninterrupted. Of this there is no better evidence than the series of lectures on State Medicine and Public Health, delivered in the College since 1888 under the bequest of Dr. Gavin Milroy, a true benefactor whom it is my duty to commemorate specially on this occasion.

I am content to close this portion of the history of the etiology of fever in 1858. In that year Pasteur sterilised water, and by a simple-looking experiment finally solved the problem of the relation to each other of the two extrinsic elements of infection—contagia and their media.

Achievements of Early English Sanitarians.

This review, necessarily brief and fragmentary as it is, serves to illustrate how much can be achieved by immediate, well-directed, and exact observations, unprejudiced consideration of facts, and intelligent and successful application of the resulting knowledge by way of experiment conformably with Harvey's model. To me the most instructive features of it are the incalculable amount of public good that was effected by English sanitarians before either the nature of contagion or the rôle of the media of its growth and spread was discovered; and that ignorance in these two respects did not shake their conviction of the existence of what they could not define, nor tempt them from their field of practical work into idle speculation or into heartless resort to antiquated authority. They were true to Harvey's memorable commentary on the criticism passed by some of his contemporaries on his own work "as throwing obstacles in the way of their explanations" of the phenomena of the circulation in disease: "the facts cognisable by the senses wait upon no opinions and the works of Nature bow to no antiquity. ..... There are many things we admit in physiology, pathology, and therapeutics the causes of which are unknown to us—the causes of putrid fevers ..... among the number."

OBSERVATIONS ON FEVER IN ITS CLINICAL RELATIONS.

Let me now return to the year 1657, and from the death of Harvey to the present time survey the other field of observation of fever—of fever in its clinical relations. Physicians in hospital and in better-class practice, not immediately concerned with a pestilence but with cases of illness in individual patients, studied causation in its bearing on treatment only. In the clinical phenomena of fever and in its course towards either recovery or death they, like their predecessors from immemorial times, recognised manifestations of a struggle between morbific matter, infection, τὸ θεῖον, and a power possessed by the body of spontaneous resistance and recovery, a *vis naturae*.

The Views of Sydenham and Cullen.

According to Sydenham, the remote causes of fever are particles in the air which insinuate themselves into the body and are mixed with the blood, and also various ferments or putrefaction of humors which are detained in the body beyond their due time, the auto-infections of to-day. Fever, he says, is Nature's instrument whereby she separates the impure from the pure: inordinate commotion of the blood, the cause or companion of fever, is stirred up by Nature. Cullen, who practised a hundred years later, and with Sydenham may be taken to represent the practical type of physician of those times, describes the remote causes of fever as chiefly some matter floating in the air, specific contagions and miasmata, and the proximate cause as the reaction of the system to the remote causes, "the same," he says, "with what Hippocrates called Nature." And the main indication or object of treatment of fever is to assist Nature in her methods.

So far physicians of the seventeenth and eighteenth centuries worked on sound lines. Their doctrine of fever was essentially the same as the accepted pathology of fever at the present time, "a wonderful specimen," says Sir Thomas Watson, "of the sagacity of the older physicians—of the despised wisdom of our forefathers." And to this extent they were in mutual agreement.

But they were not satisfied. Difficulty, error and disagreement commenced with attempts to interpret the details of the struggle in the body—the individual symptoms of fever. They neglected Harvey's counsel to take time and gather facts. Let us be fair to them. Unless they were pure empirics like Sydenham, who scoffed at their pseudo-scientific doctrines and methods, they had to find in the symptoms of fever and in its course individual indications for the management of the rigors, the vomiting, the headache, the delirium, the increasing debility, and the other kinds of disorder and distress that called for relief. Where knowledge failed them as a guide they turned to speculation. This they did although they did not know in what either of the two antagonists in fever, contagion and the *vis medicatrix Naturae*, consists. The constitution of contagion they gave up as an insoluble problem. Sydenham declares that the remote causes of fever, whether particles in the air or putrefaction in the body, "are wholly inscrutable," "have no manner of commerce with the senses," "taking up the vain speculations of curious men," and if known would be unnecessary for use as indications in treatment. "We know nothing," says Cullen, "of the nature of contagion that can lead us to any measure for removing or correcting it"; and by him the question remained wholly disregarded.

The Many Doctrines of Fever.

On the other hand, speculation and dissent were endless respecting the *vis Naturae*—that is, the structural and functional constitution of the living body, and on the question how and in what respects it is *medicatrix*. Thus there arose in succession the many different doctrines of fever (as many as there were of the nature or secret of Life itself, on which in large measure they were based) that constitute so large a part of medical literature from the time of Sydenham to the beginning of the nineteenth century. Indeed, the same story of fresh and ever diverse speculations and therapeutic systems continued well into the reign of Queen Victoria. And, paradoxically, the advance of physics, chemistry and physiology by Newton, Boyle, Mayow, Lower and others stimulated premature speculation instead of controlling it. In each new doctrine of fever, as it arose, one can trace the influence of a recent discovery in science, adapted to support some theory of life and disease, woven into the tangled web of mediæval dogma.

Sylvius, impressed by Harvey's discovery, asserts that fever proceeds from increased velocity of the circulation. Effects of the publication of the "Principia" are seen in the views of Archibald Pitcairn and his friend Lorenzo Bellini, who explained all the phenomena of fever as the results of mechanical processes; and in Boerhaave's teaching that it is to be accounted for by increased capillary resistance and "too quick contraction of the heart" through the medium of the nervous system, including the cerebellum.

Cullen as distinctly was impressed by Haller's discovery of the irritability and sensibility of the tissues. His statement of the doctrine of fever will serve as sufficient illustration of the way in which what you, Sir, call transcendental

speculation usurped step by step the place of sober description. According to him, the remote causes of fever act on the nervous system and produce debility in the action of the extreme vessels. This, through the intervention of the *vis medicatrix Naturae*, forms an indirect stimulus to the circulation, and vascular spasm and increased action of the heart are the result. The energy of the brain and the extreme vessels is thereby restored, the spasm is overcome, and sweat and other excretions are set free. On the other hand, John Brown held that fever was an asthenic state of the system arising from an obstruction of the natural stimuli, or from exhaustion, direct or indirect, of its excitability.

At the begining of the nineteenth century comes the doctrine of Broussais, supplemented by the theories of Clutterbuck and of Armstrong, that fever is always symptomatic of local inflammation. From this doctrine, and the depletive treatment based on it, there was early reaction. In 1834 Graves strongly condemns "general explanations of the causes of disease" as having "more than any other circumstance contributed to retard the progress of medicine. We live," says he, "among systems." Nor did matters soon mend. Within the lifetime of some of us here to-day the pathogeny of fever, and the notions of the causation of disease in general, appear to the student of the history of medicine to have been chaos.

Facts Established for Centuries Displaced by Assumptions.

To such a pass had unsupported assumption displaced knowledge that facts established for many centuries were discarded. In whatever way we may account for it, men for a time lost hold of the two causal agents in fever which, as we have just seen, were recognised as clearly by Sydenham as they are recognised to-day—contagion and spontaneous resistance. With regard to the latter, Sir John Forbes, as late as 1857, in a work on "Nature and Art in the Cure of Disease," protested against the prevalent neglect, indeed the ignorance, of a natural influence making for recovery. As for the nature of contagion, even Stokes in his "Lectures on Fever," after combating a view prevalent at the time that insanitation alone without contagion may originate fever, expresses the opinion that "the same exciting cause—at least as far as we can see of it—is capable of producing different kinds of fever in different persons"; and, observing that the production of fever was inconstant while insanitation was constant in many parts of Ireland, he quotes without dissent Graves's opinion that they were not to expect any notable diminution of fever from the operation of improved drainage, improved habits of cleanliness, and increased comforts. Sir Thomas Watson in 1857 also has to argue at length in favour of the existence of contagion, and in the same connexion he confesses that, until Jenner's differentiation of typhoid from typhus, he had taught that the differences in the aspect and phenomena of continued fever depended more on the epidemic constitution than on any essential difference in the nature of the disease itself, or in the virus from which it sprang.

This is a moving chapter in the comparatively recent history of medicine, where we find men of higher intelligence than many of us could claim, keen, methodical, laborious, accurate observers, searching in vain for a rational pathology of fever which an almost immediate future was going to reveal. And coming to Murchison, one of my own teachers, after Jenner the highest authority on fevers in England, it is difficult for me to realise that I am already separated from him by the great interval of doctrine if not of time that these words of his published in 1873 reveal:—

> We have it in our power not only to arrrest the spread of continued fevers, but in many cases to prevent their origin. The parasitic theory rests solely on analogy and is unsupported by facts. If all contagious diseases can arise in no other way than by contagion, their germs must be both omnipresent and indestructible by time. There are certain contagious diseases, such as erysipelas, pyæmia, and puerperal fevers, whose origin *de novo* may be said to be a matter of almost daily observation and which, in fact, we have almost the power of generating at will. For these reasons and others there are good grounds for believing that contagious fevers have occasionally an independent origin.

COMPARISON OF THE WORK ACCOMPLISHED IN THE TWO FIELDS.

Thus the 200 years passed; and now we may compare the results achieved in the respective fields of observation of fever. Preventive medicine was by this time well founded on established facts—the existence of contagion, the circumstances under which it is bred, the media by which it reaches man, and the influence of insanitation in favouring both individual exposure and individual receptivity. Clinically, on the other hand, physicians of the mid-Victorian period were in respect of the pathology of fever in no better—indeed, partly in less good—position than Sydenham: the very existence of contagion questioned, the specificity of the different fevers disputed, spontaneous generation of fevers supported by abundant argument, spontaneous resistance and recovery as provisions inherent in the body ignored or mentioned in derision. A single exception, the confirmation of the difference between typhus, typhoid and relapsing fevers—already maintained on the continent and in America—was the result of work conducted on strictly Harveian lines mainly by Jenner. Events as a whole proved the wisdom of Harvey's counsel and the need of frequent exhortation to make it, in his own words, "our first duty to inquire whether the thing be or not before asking wherefore it is."

If I have succeeded in convincing you by the illustration I have chosen which of the two methods of studying out the secrets of Nature is the correct one, judged by their respective results, let me now ask you to be generous to the observers whose method stands condemned. Many physicians of the period made and recorded observations of great value on the clinical characters and course of different outbreaks of fever. And the problems before them were of a different order from those which met the sanitarian, and more difficult of solution—indeed, they were insoluble without the help of pure science. Two great secrets of Nature had to be searched out, and the materials of which the keys were forged that were to unlock the secrets had to be found—anatomical, chemical, biological and pathological. For this event, being practising physicians, they did not wait. After all, the very errors into which they fell, in their desire to help their patients, provoked discussion and research, and indirectly promoted progress. Far better the trial and error of those times than the stagnation of thought and effort of the dark ages from Galen to Vesalius.

DISCOVERY OF THE NATURE OF CONTAGIA AND IMMUNITY.

The confusion of view that surprises us in this record as prevalent so late as 1873 was one of the signs of dawn of two great discoveries, which were presently to illuminate the field of the pathology of infections; indeed, the whole field of the origin of disease. The period between the years 1859 and 1880 is all-eventful in the history of the pathology of fever and of infection generally. The contagia of certain febrile diseases were proved by Pasteur, Lister and Koch to be living vegetable organisms; those of certain other febrile diseases by Lewis, Obermeier and Laveran to be living animal organisms. Contagia were parasites, and vegetable parasites were linked up with animal parasites, already recognised from the earliest ages of medicine.

The two fields of observation which I have surveyed now became common ground; and the sanitarian, the clinician and the family doctor found themselves working as you, Sir, have said on adjacent areas inseparably connected. And the greatest modern triumph of preventive treatment was gained when Lister in the practice of remedial treatment demonstrated the success of his antiseptic method.

Close on the discovery of the essential nature of contagia came another, complementary of it, the discovery of immunity, passive and active, the product of a function resident in the blood, and exercised by it on occasion whether natural or artificial—that is, experimental. This second discovery, based essentially on the first, was the work of Roux, Buchner and Behring on the chemical side, of Metchnikoff on the biological side, phagocytosis connecting fever once more with inflammation. The faculty of immunity was the second agent in fever, so long searched for in vain. The discovery of it was a fresh recognition of a fact established at the latest in the time of Hippocrates. The *vis medicatrix Naturae* was re-established after its temporary dispossession and degradation, and by a new method—by experiment and under a new name.

And now the question arose, How come this spontaneous resistance to contagia and this spontaneous recovery from the effects of them, *vis conservatrix et medicatrix*, to exist? Was there nothing to be found, by what Harvey in his fifth Canon called "the general study of Nature," to serve as a link between parasitism and immunity in fever?

The link was already found in evolution. Darwin's "Origin of Species" had appeared in 1859, the year in which Pasteur succeeded in sterilising water. It is now accepted that our body is protected against unfavourable influences under the law of the survival of the fittest, which governed, and still governs, its evolution; and that when the provisions for protection prove insufficient, and disorder or disease arises in consequence of the evolution of man being still incomplete, whatever his destiny may be, other provisions, also the result of natural selection, come into play, controlling, or at least moderating, morbific agents and their effects, and repairing structural and functional damage. And presently it came to be accepted, further, that artificial selection can be employed to assist natural selection, and that this is to be done by public sanitation, which not only deals directly with contagion and the media of infection, but by improving the material and moral circumstances of living also builds up resistance in the individual from childhood onwards, and through the individual ultimately in the race, and to unfavourable influences of many other kinds than organised infections.

HARVEY ON THE NATURAL HISTORY OF LIFE AND DISEASE.

The history of the development of the pathogeny of fever shows us that men as well as facts had to be waited for. Darwin, Pasteur, Lister, Koch, Metchnikoff and Behring had to arise. But let me remind you that they have to share with Harvey the honour of reaching their great inductions.

Now and again in the course of his writings Harvey discloses trains of thought on the natural history of life and disease. In pursuing his immediate investigations he comes on some fact correlated with that subject. He grasps the significance of it as only a genius could grasp it, states the same in a few pregnant words, and turns from it back to his present concern.

I will read to you a few passages from "De Generatione." The first of these relates to the nature and spread of contagion.

> Let physicians ..... cease to wonder at what always excites their astonishment—namely, the manner in which epidemic, contagious and pestilential diseases scatter their seeds and are propagated to a distance through the air, or by some "fomes," producing diseases like themselves in bodies of a different nature, and in a hidden fashion silently multiplying themselves by a kind of generation, until they become so fatal and with the permission of the Deity spread destruction far and wide among man and beast.

The second passage relates to the *vis medicatrix Naturae*. What opinion did Harvey offer of it and its significance? No opinion. Of all the observers in these 200 years, as far as I can find, Harvey alone offers us an experiment instead.

> I have myself (says he) for experiment's sake occasionally pricked my hand with a clean needle, and then having rubbed the same needle on the teeth of a spider I have pricked my hand in another place. I could not by my simple sensations perceive any difference between the two punctures. Nevertheless there was a capacity in the skin to distinguish the one from the other, for the part pricked with the envenomed needle immediately contracted into a tubercle, and by and by became red and hot and inflamed, as if it collected and girded itself up for a contest with the poison for its overthrow.

A perfect experiment, proving, as Harvey puts it, that "the flesh itself readily distinguishes a poisoned wound from one that is not poisoned."

Next, by a simple observation, unpremeditated and unprejudiced, but to him full of significance, he discovers in the organs of defence and escape in animals another order of provisions possessed by the body against disease.

> To those animals (he tells us) to which Nature has given vast strength she has also presented weapons in harmony with their powers; to those that are not thus vigorous she has given ingenuity and cunning and singular dexterity in avoiding injury.

The most highly developed means of protection Harvey sees in intelligence.

> Man (says he) comes into the world naked and unarmed, as if Nature had desired that he should be guided by reason rather than by force; therefore did she endow him with understanding and furnish him with hands, that he might himself contrive what was necessary to his clothing and protection.

Having thus outlined in a few words the different orders of provisions for survival in the struggle for existence possessed by the individual—automatic, instinctive, and voluntary—Harvey surprises us by proceeding in the next sentence of "De Generatione" to forecast the correlated law of sexual selection.

> Ornaments of all kinds (according to his observations) such as tufts, crests, combs, wattles, brilliant plumage, and the like. o say nothing of such offensive weapons as teeth, horns, spurs, and other implements employed in combat, are more frequently and remarkably conferred upon the male than the female ..... the subject of dispute being no empty or vainglorious matter, but the perpetuation of the stock in this line or in that, as if Nature had intended that he who could best defend himself and his should be preferred to others for the continuance of the kind. ..... Nor is this ornamenting anything adventitious and for a season only: it is a lasting and special gift of Nature, who has not been studious to deck out animals and especially birds only, but has also thrown an infinite variety of beautiful dyes over the lowly and insensate herbs and flowers.

These four brief discussions constitute a single great conception, in which Harvey, by way of experiment and intelligent observation which it has been my privilege and duty this day to exhort you to follow, came near to unlock the very secret of Nature's secrets, the relativity of life, the reaction of Man to the influences of his environment, whether favourable to his existence and health, or unfavourable to them—constituting the causes of disease and death. This conception is alone sufficient to justify the admiration and reverence which the College all these hundreds of years has entertained for the man whose work and character are our chief glory.

And in this connexion let me once more impress upon you the consideration that Harvey is distinguished from his early followers by his restraint from speculation, the self-restraint of the true scientist. Having revealed his conception of the ways and working of Nature as it occupied his mind, he represses himself and resumes the place and attitude of a simple, patient observer, content to accumulate and record facts, and to leave speculation to time and his successors. Harvey's prevailing hope and desire was that his work and his method of work might be continued, that the prospect which he saw opening before him, but still distant, might one day be reached by others. Truly says John Simon of Bacon and Harvey:—

> Noble eloquence and nobler example had taught lessons which never again could be lost from men's minds as to the spirit and method of all scientific research—that system of modest and patient interrogation through which alone any knowledge of Nature will grow.

Post Scriptum.—The Orator desires to acknowledge the assistance obtained in the preparation of this study from Simon's "English Sanitary Institutions," and Dr. Charles Creighton's standard treatise, "A History of Epidemics in Britain."

Presidential Address
ON
THE NATURE AND DEGREE OF SPECIFIC DIFFERENCES AMONGST BACTERIA.

Delivered before the Pathological Section of the Royal Society of Medicine on Oct. 21st, 1913,

BY F. W. ANDREWES, M.D. OXON., F.R.C.P. LOND.,

PATHOLOGIST AND LECTURER ON PATHOLOGY AT ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—I am deeply conscious of the honour of becoming the President of this section of our society, and I have been no less alive to my responsibilities in preparing the address which it is customary for the new officer to deliver. Such an address should, I hold, be devoted to a general rather than to a special subject, and I have been bold enough to choose one which presents many difficulties—the Nature and Degree of Specific Differences amongst Bacteria. It is time that we faced its difficulties fairly, and I propose to look at the subject from a broad biological standpoint, and to discuss what our present knowledge enables us to affirm as to the existence, amongst bacteria and similar microscopic organisms, of the limits between species which we are accustomed to recognise amongst more highly organised creatures.

STAGES IN THE CLASSIFICATION OF BACTERIA.

The science of bacteriology is a new one and it was necessarily approached, and for long pursued, under the preconceptions derived from ordinary botany and zoology. Darwin had, indeed, freed our minds from the idea of absolute fixity of species. We were prepared to admit the evolution of one species from another, but with the idea that t was a slow secular sort of process. We knew that in

certain successful or "dominant" genera variation was more rapid than in others, and that here specific limits were less sharply defined. Botanists, for example, disputed as to whether there were four species of bramble in the British Isles or many times that number. But in spite of these occasional difficulties we believed that, as a rule, we ought to be able to label a given animal or plant with a generic and specific name representing at once its real distinctness from, and its relation with, allied forms.

And so it came about, in the earlier days of bacteriology, that every observer who studied the microbes of a town water-supply, or of sewage or air, baptised the bacteria he found with an airy confidence that he was naming species as good as those of the botanist. His efforts seem almost useless to us, and we are apt to complain of the imperfect nature of his descriptions, but this was a stage through which bacteriology had to pass.

Then came the period at which the biological properties of bacteria were more fully studied. We learned their metabolic powers, their capacity to utilise this and that foodstuff, and to cause this or that chemical change in the medium in which they were growing. Further, we learned to associate these properties with the varied capacities of bacteria for causing disease. With this knowledge, which was a real advance, came at first a greater apparent certainty in discriminating between allied forms. This coccus injected into a mouse causes a fatal septicæmia; another apparently similar coccus produces no effect: clearly they must be distinct species. This bacterium ferments lactose; another, otherwise like it, does not; they cannot be the same sort.

Still more recently the conviction has been forced upon us that such biological properties have less absolute value than we at first supposed. It is clear that they may at times be gained and lost with surprising rapidity. I need not remind you how easily pathogenic properties lapse under cultivation, or how, as we know from the work of Twort, Penfold, and others, a bacterium may acquire the power of fermenting a sugar continuously presented to it.

And, finally, it has become apparent that there are characters, probably chemical, but the nature of which is only partially unveiled, betrayed by the serum reactions which may still more minutely differentiate otherwise similar forms of bacteria. There is, for example, no means of distinguishing between the members of the Gärtner group of bacilli save by the agglutinins which they severally evoke, and even here the differences are quantitative rather than absolute.

Starting, then, with the *a priori* conviction that we were going to find amongst these lowly protophytes species as definable as those with which we had been accustomed to deal amongst higher plants, we are now compelled to admit that, in spite of constantly increasing refinements in our methods of study, and, indeed, partly as a consequence of these refinements, the term "species," at least among certain groups of bacteria, has become an extremely elusive one to define.

THE NATURALIST'S CRITERIA OF SPECIES.

This, then, is the problem which I ask you to face, not with the hope of solving it at the present time, but rather to set our ideas in order. Before considering what meaning we are to attach to the term "species" amongst bacteria we must first have a clear idea of the meaning now attached to it by ordinary naturalists. We nowhere find the cult of specific differences so ardently pursued as amongst entomologists, and the very subject of my present discourse, in its application to insects, was chosen by my friend Professor E. B. Poulton in his presidential address to the Entomological Society in 1904. He pointed out that the doctrine of the absolute fixity of species, which rests on the theological dogma of special creation, is not of great antiquity, probably originating towards the end of the sixteenth century. Linnæus, of course, held it with firm conviction, and it was only in the middle of the nineteenth century that the writings of Herbert Spencer, and above all of Darwin and Wallace, began slowly to convince current opinion in the new direction that species were not fixed but derived from pre-existing species. In Darwin's own words: "Hereafter we shall be compelled to acknowledge that the only difference between species and well-marked varieties is that the latter are known or believed to be connected at the present day by intermediate gradations, whereas species were formerly thus connected."

To-day we are wholly freed from the doctrine of the immutability of species. We continue to use the term because it conveniently expresses our notions as to the relations of a given group of individuals, but it is in a measure a subjective rather than an objective conception. The naturalist recognises and defines what he means by a species according to several criteria. These are: (1) morphological characters, (2) capacity or incapacity for interbreeding, (3) known descent from a common ancestor, and in certain cases (4) geographical distribution.

Poulton, as an entomologist, would generally define a species as a freely interbreeding group of individuals derived from a common ancestry. A botanist might not accept this definition, for in many genera of plants—e.g., Primula, Saxifraga—undoubtedly distinct species interbreed with some freedom, but in a general way this is what a naturalist means when he speaks of a "species."

THE CRITERIA OF THE BACTERIOLOGIST.

But when the bacteriologist attempts to apply such criteria as these he is baffled, and this for more than one reason. In the first place the test of interbreeding is inapplicable in a group in which sexual reproduction and even conjugation are unknown. The naturalist finds mutual fertility or sterility a useful criterion in judging of specific rank, but over and above this, the mere fact of the conjugation of two different cells in reproduction plays an important part in keeping the characters of a species constant. The fusion of two independently varying individuals (or, in the case of higher organisms, of the reproductive cells of such individuals) tends to efface the results of chance variation and bring the product back towards the average of the species. The absence of sexual reproduction affords therefore one reason for the extreme variability of bacteria. Further, it would seem possible that Weismann's doctrine of the non-inheritance of acquired characters may not apply to organisms multiplying exclusively by binary fission; bacteria present a continuity not merely of the germ-plasm, but of the entire somatic plasm.

In the second place the inordinate rapidity with which bacteria multiply allows the effects of environment to become apparent in a very short space of time. It is possible that such effects are stamped with greater readiness on the sensitive and labile protoplasm of unicellular organisms than on the more complex structure of higher types. In any case natural selection must act with greater intensity upon creatures which can pass through 20 or 30 generations in a day than upon those which reproduce their kind only once or twice a year.

The high degree of variability observed amongst bacteria seems adequately explained by the foregoing considerations, and I need hardly remind you how great it is, especially in regard to the higher physiological properties such as pathogenic power. Sooner or later this seems always lost under cultural conditions, unless maintained by occasional animal passage. The natural tendency seems to be towards loss of virulence in the absence of opportunity for its exercise, and the mechanism by which animal passage revives the power would seem to be one of natural selection in its crudest form. The feebler invaders are destroyed by the defensive mechanisms of the body and the final invading force comes to consist of the highly competent descendants of those which have best been able to resist destruction. This restoration of pathogenic power may occur in a few days—almost in a few hours—and the process affords an excellent example of the principle of the "survival of the fittest" in a community in which extreme rapidity of reproduction gives natural selection an opportunity elsewhere almost unparalleled.

Other physiological properties may be lost and gained by bacteria in a somewhat similar way though with less rapidity. The power of producing pigment or of utilising a certain sugar is not infrequently observed to lapse under cultivation.

It follows that it is only with extreme caution that such characters as pathogenicity or metabolic capacity can be regarded as of specific value. Of the criteria employed by the ordinary naturalist in discriminating between species one only can be used by the bacteriologist—namely, the morphological one. Evidence of descent from a common ancestry is usually wanting under natural conditions, though available in experimental laboratory work.

GENERIC CLASSIFICATION.

Morphological differences are, however, slight or absent between closely related bacterial forms, and are hence of almost no value in discriminating between species, though they are of fundamental importance in defining the larger systematic groups of bacteria. The great families—cocci, bacilli, and spirilla—are based essentially upon morphology alone. Within these families, again, we can clearly recognise natural groups of the value of genera. Thus, amongst the cocci we see such generic groups in the streptococci, the Gram-positive staphylococci, the Gram-negative cocci, the sarcinæ, the flagellate cocci, &c. Similarly amongst the bacilli we recognise the coli-typhoid group, the diphtheroids, the sporing anaerobes, the acid-fast group, and many others. Some of these groups are small, others very large, but in the case of almost every bacillus which has been adequately studied we can "place" it in one or other of the groups I am speaking of, and this with little doubt or hesitation. Actual generic names have been proposed by Migula and others, and have perhaps only failed to gain general currency because they contained so many syllables.

The characters in virtue of which we refer an organism to one or another of these generic groups are largely morphological—structure and configuration, presence or absence of spore formation, number and distribution of flagella, if present. Or, if they are not morphological, they depend upon some ingrained chemical peculiarity in the bacterial body manifested by such properties as acid fastness or a positive reaction to Gram's stain. But we do not employ, as generic criteria, such characters as pathogenicity, fermentation reactions, or serological tests. There is no need to do so, and, indeed, generic distinctions became apparent early in the study of bacteriology and gained general recognition long before the introduction of many of these modern refinements in diagnosis.

If the foregoing facts are true—and I do not think they will be disputed—we are entitled to conclude that although bacteria are more variable than the majority of living creatures, they are by no means indefinitely variable. The variations are seen within the generic group limits but do not transgress these. No one would assert that by any known means could a streptococcus become transformed into a sarcina, or an acid-fast bacillus into a coliform organism.

It is probable that generic differences are of great antiquity. We may reasonably conjecture that bacteria were amongst the earliest forms of life, and, indeed, there is some scanty evidence of their existence in such early geological periods as that of the coal measures. The comparative fixity of generic forms would reasonably be explained on the supposition of their antiquity.

THE QUESTION OF SPECIFIC TYPES.

But I must now pass from this relatively easy question of generic classification to the subject I particularly wish to consider—that of the existence and permanence of specific distinctions within the limits of a genus. In the first place, it must be observed that much more variability is to be seen in some genera than in others, and the general rule may be laid down with some confidence that small genera, containing only one or two forms, show much more constancy than the large genera. Thus the anthrax bacillus has few or no close allies; it is almost a genus to itself and it shows hardly any variability. This is true also of micrococcus melitensis and bacillus mallei. In contrast to these we find such genera as the streptococci, the diphtheroids, and the coli-typhoid group, which are excessively abundant in nature, rich in the number of their forms, and present the highest degree of variability. It is in such genera as these latter that the chief disputes have arisen amongst bacteriologists as to what are species and what merely varieties. As I have argued elsewhere, these genera are those which biologists term "dominant genera"—i.e., groups which have succeeded, and are succeeding, in the struggle for existence; witness their abundance. And the multiplicity of the forms which they present is due to the property already mentioned, and the reasons for which I have discussed—viz., the readiness with which physiological characters are gained and lost amongst bacteria under the direct influence of their environment, such modifications being handed on by the process of direct binary fission, which is the only means of multiplication in this group, without the check imposed by sexual propagation.

This I believe to be a reasonable explanation of the chaos of related forms seen, for example, in the bacillus coli group and amongst the streptococci. I by no means wish to make the general assertion that there are no such things as strictly defined species amongst bacteria. On the contrary, it is easy to adduce examples of such species, readily recognisable, and about which no doubt or confusion exists. But it is possible that we have fallen into error in supposing that *all* bacteria must necessarily conform to well-defined specific types; and I venture to put forward the suggestion that this is not the case in the dominant genera of which I have just spoken. We have been striving by means of ever newer and more refined tests to define that which is undefinable because it does not definitely exist.

If we can accept such doctrine as this, that in some bacterial groups (and these, groups with which pathologists happen to be particularly concerned) rigid specific limits have actually no existence, we shall, I think, gain a good deal. We may, for example, leave off quarrelling as to the specific value of fermentation tests and serological reactions, and bend our minds to doing the best we can with the mass of related forms presented by dominant bacterial genera. Nor, I think, is the task of classification by any means a hopeless one if it be approached in the right spirit and with a due apprehension of the real state of affairs.

The view to which I have been gradually led, and to which partial expression was given in my joint paper with Horder on the Classification of the Streptococci seven years ago, is as follows. We actually see before us, in such genera as the streptococci or the bacillus coli group, a mass of variable forms, representing, as it were, the melting-pot in which species are made, and from which even now species are emerging. We may, if we will, actually trace the process of emergence by the application of suitable methods, and all the stages of the process can be watched. Thus, from the bacillus coli group we see the typhoid bacillus already emerged as a species almost fully fixed and defined, while in Salmonella we have a subgroup of coliform organisms struggling upwards into differentiation, separable as a subgroup, but with specific limits recognisable only by the doubtful criteria of serology. As for bacillus coli itself we have a set of tests, in virtue of which we assert a given organism to be the classical bacillus coli communis, but every bacteriologist knows that its varieties are almost infinite. It is eminently likely that in far distant æons certain of these now labile forms will crystallise, under the influence of a persistent environment, into species as definite as we see in other bacterial genera. Such speculation is, however, idle: the practical questions for us are what terminology we are to employ to-day, and how we are to set a value on the tests which are at present at our command, so that we may obtain from them information of use to us in our everyday work.

THE EMPLOYMENT OF THE STATISTICAL METHOD.

In the study of an infinitely variable group of closely related forms I know of only one method capable of helping us—namely, the statistical one. We may take any arbitrary, but convenient, set of characters and study their frequency of occurrence in a large series of strains. I may perhaps be permitted to quote from the paper by Horder and myself published in THE LANCET in 1906,[1] because I do not know how to state the case more concisely than is there attempted.

> When any arbitrary set of characters is taken as a basis for the classification of a group of natural objects the same phenomena are usually seen—large groups of like objects connected by small groups which differ from them in only one or two particulars. If the numerical frequency of each individual like group is represented by the proportional height of a vertical line and the lines are arranged in series the commoner types stand out boldly above the rarer ones. Only in nature they are plotted out, not in linear series, but in space of two dimensions, as it were, so that the common types stand out as mountain tops above their fellows, each mountain connected by valleys of intermediate types with many of its neighbours. If now the mountains were cut off by a horizontal plane half way up their sides and attention were paid only to the mountain tops, disregarding the valleys, we should have the popular conception of species. The biologist, on the contrary, is more concerned with the intermediate types in the valleys, as illustrating variation and the connexion between allied species. In some groups of plants and animals the mountains are few and high and the valleys very deep. These are the groups which are, so to speak, in a stationary condition—which are not rapidly varying and adapting themselves to new conditions. In

[1] THE LANCET, Sept. 15th, 1906, p. 711.

other groups, which biologists call "dominant genera," the mountain tops are numerous but not so high and separated only by shallow valleys: these are the groups which are at the moment succeeding in the struggle for existence.

I still believe the words I have just quoted to represent the facts for such groups as the streptococci and the colon group, and I may remind you that about the same time Winslow, working at the classification of the cocci in America, used somewhat similar methods and arrived at the same conclusions. In statistical study of this sort it does not much matter what characters are taken as criteria provided that they are uniformly applied over a sufficiently large series of individual examples. In any case we shall find certain predominant groups of individuals giving the same set of reactions connected by smaller intermediate groups. We are witnessing the evolution of species under the influence of environment; the most commonly occurring types are "species in the making," and are aptly termed by Winslow "centres of variation."

In conjunction with Horder I tried to apply the principle to the streptococci, using as an arbitrary set of tests the sugar reactions devised by Gordon. We were very careful to avoid any claim that the predominant types, revealed by the application of these tests over a series of 1200 strains of streptococci, deserved specific rank, but we thought, and I still think, that the tests are of value in discriminating the sorts or varieties of the maze of allied forms met with in this group. Similarly, I hold the analogous tests employed for the colon group, or the diphtheroids, to serve a very useful purpose. I am convinced that in all these dominant genera we are not dealing with fixed species but with relatively labile forms. It has been objected to the sugar tests, notably by Ainley Walker, that they are insufficiently constant to be of any differential value, and he has certainly been able to show that under laboratory culture they may present considerable variation. My own experience has not been in favour of such a degree of variation as he has met with, though I know that variation spontaneously occurs, and that it may readily be induced by suitable means. I am not, however, disposed to admit that the fact of induced variation under cultural conditions seriously affects the value of biological tests for bacteria, applied in the manner I have indicated. Although the principles involved are of general application, I may perhaps be permitted to draw my illustrations from the streptococci because they are the group with which I have chiefly worked, and it has been amongst them that the value of the sugar reactions has most vigorously been attacked.

STREPTOCOCCI AND THE SUGAR TESTS.

I regard the streptococci as a typical example of a dominant genus which has succeeded in life by attaching itself, as a saprophyte, to the animal body, where, under the varying physiological conditions present, it has acquired great adaptability and become an extremely variable genus. The environment offered by the mouth is not the same as that offered by the large intestine. The conditions offered by the large intestine are not the same in herbivorous and carnivorous animals. When a streptococcus has invaded the living tissues and set up suppuration, its environment is very different from that met with in the alimentary canal. When we apply any set of arbitrary tests—be they sugar tests or others, such as pathogenicity for animals, resistance against drying, ability to cause hæmolysis, or to form sulphuretted hydrogen—to streptococci freshly isolated from one or another of these different environments, we find differences. In the mouth we find a number of different forms, but one form, giving a positive reaction to certain tests, outnumbering other forms. In human fæces we also find many forms, many of them identical with those of the mouth, but again one sort, different from the common mouth form, outnumbering any other one form. In horsedung, again, we find the commonest type to differ from that of human fæces. If we isolate streptococci from cases of erysipelas, phlegmonous inflammation, or suppuration, again we find a great predominance of strains giving one particular set of reactions. I regard the forms in question as bearing the biological stamp of their recent environment, and it is my experience that they retain that stamp in cultivation for some little time and often for months or years. It is true that they may sooner or later lose it, but for practical purposes this does not much matter. The tests help to reveal what a recently isolated strain of streptococcus did last, and what, in the light of previous experience, it is likely to do next. In other words, they are of practical value in diagnosis and prognosis.

It is doubtful whether the variations revealed amongst streptococci by biological tests are of specific value. I am content to look upon them as potential species, not yet fixed, or as "centres of variation," and I think it is justifiable to employ definite names for them. The usefulness of the tests must be judged by the results of their employment. If the sugar reactions of streptococci are as valueless as some would have us believe, their employment should land us in ridiculous inconsistencies. This is not my experience; indeed, I have found them of the greatest value, especially in public health work. I may be forgiven if I quote one or two instances from work already published. 1. In an investigation into the air of drains I found that the most abundant streptococcus in the local sewage presented a certain set of characters, and that the majority of the streptococci obtained from the air of the drain presented the same set of characters, whereas those obtained from fresh air presented a totally different group of characters. I felt justified in inferring that the streptococci of the drain air were derived from the sewage, and since that time an abundance of independent data has, I think, confirmed the conclusion. 2. Again, the common streptococci to be found in fresh air in London present a certain peculiar facies in their metabolic powers. Arguing that horsedung formed the most abundant organic ingredient in London air, I quantitatively examined fresh horsedung and found that by far the most numerous organisms were streptococci of precisely the same characters as those with which I was familiar in fresh air. The conclusion as to the source of the air streptococci seems clear and has been confirmed by Winslow in America.

It would be easy to multiply similar examples, but I will mention only one other—viz., that Gordon was able to demonstrate streptococci having the same set of characters as those most abundant in normal saliva, in the ventilating shafts of the House of Commons when the House is sitting, but not at other times.

It will, I think, be admitted that such results as I have quoted, far from being inconsistent and misleading, are reasonable and consistent, and support the idea that the sugar reactions of the streptococci, to the intelligent application of which they were alone due, have a definite value. And this value seems to me to lie, not in attempting to force every streptococcus into a cast-iron scheme of specific nomenclature, but in indicating the "centre of variation" to which any given strain appertains and in giving a clue to the metabolic conditions which have most recently set their stamp upon the strain.

I trust that I shall be pardoned for having referred at such length to the sugar tests for streptococci. I have done so because I wished, in face of the adverse criticism which they have of late received in some quarters, at once to defend them and to make clear my own opinion as to their limitations. I hope I have made it plain that I believe neither in the so-called "unity of the streptococci" nor in their division into fixed and immutable species. I hold them to be a labile group from which types are emerging, which can be recognised by suitable methods, but which are at the present day for the most part undeserving of specific rank.

THE BACILLUS COLI GROUP.

If we turn to the B. coli group we find somewhat the same state of things, but complicated by the fact that evolution has here advanced much further, so that not only have certain fairly definite species emerged, but even the genus itself is becoming, or has become, broken up into a number of rather ill-defined subgenera. Of this we have the strongest of all evidences—viz., morphology; for whereas some are always richly flagellate, others have but few flagella, while in others motility is totally absent and no flagella are demonstrable. Such distinctions are at least of subgeneric value. I need hardly remind you of the terms which are creeping into use for such differences—the dysentery group, the typhoid group, the Friedländer group, and even such definite names as Salmonella, Pasteurella, and so on. But within the limits of the individual groups we find still present in many cases a number of allied forms which are only imperfect species. Here, again, the sugar tests are used widely for differentiation, and, in spite of some

degree of admitted variability, are found of signal use in practical application.

Water bacteriologists lay some stress on whether or not a given strain of B. coli can or cannot ferment cane sugar, holding that if it cannot it is the genuine B. coli communis, to be treated with more respect than the variety which accomplishes this fermentation. I should not consider this test of any value as differentiating two otherwise similar organisms into separate species, but I should not therefore deride its application to the bacteriology of water. Its value here will have to be judged, not by laboratory experiments proving that the bacillus can be made to ferment, or not to ferment, cane sugar at will, but by the broadest kind of experience in which thousands of water analyses are studied in this and in other ways. Such data are accumulating, and in time a judgment may be formed. If I may so put it, the use of a test of this kind is not a matter of politics but of statesmanship.

The B. coli group further differs from the streptococci in the applicability of agglutination tests to a degree scarcely paralleled in any other genus. But this refinement of diagnosis only leaves us still more perplexed as to what we are to call species and what varieties. On general evidence no one would hesitate to affirm that B. typhosus and B. paratyphosus B were not only specifically distinct, but should even be classed in different subgenera. Yet although in most cases of human infection serological methods enable a diagnosis to be made, paradoxical cases have been described in which paratyphoid serum agglutinated B. typhosus better than it agglutinated the homologous organism and *vice versâ*. Until we know more about the physical chemistry of agglutination we must be wary of basing specific distinctions on this alone. Much has been done in the recognition of "group agglutinins" as opposed to "specific agglutinins," but it is to chemistry that we must look for a solution of the problems.

CHEMICAL EVOLUTION.

This brings me, in conclusion, to an aspect of my subject which is at the present day largely conjectural, but which is beginning to attract the attention of many workers, and which has recently been the subject of a thoughtful essay by Dr. Eccles, of Brooklyn.[2] I refer to the idea of "chemical evolution." The work of Darwin and his modern successors, on which are based our present ideas of the process of evolution amongst living beings, took account only of morphological differences between allied forms, together with the physiological differences necessarily correlated with these. But just as, before Darwin, the conception of evolution had been applied to the solar system, and indeed to the universe, so, long after his day, the progress of biochemistry is beginning to suggest its applicability to the protein molecule.

I cannot affect to speak with any authority on chemical problems, but so far as I understand the matter the protein molecule is essentially built up of amino-acids, limited in number to some 20 or more. The different specific proteins owe their characters to the proportions of these different amino-acids present, and to their relative positions in the configuration of the molecule, affording an infinite variety of combinations. To use Kossel's picturesque simile, the building stones of the protein molecule may only be as few as the letters of the alphabet, yet these can express an infinite number of thoughts. I look forward with confidence to the time when chemists will be able to explain all the differences between the proteins of different animal and vegetable species on such lines as these, together with precipitin reactions and complement deviations and all the other specific tests which we now use empirically. And further, I am fully prepared to believe that these minute structural differences in the configuration of the protein molecule have arisen by natural selection—as a result of the survival of the chemically fittest molecules in the struggle for existence of the organisms to which they belong.

If this is true, it is plain that there is a chemical evolution, underlying a merely morphological one, quite independent of morphological change, and, at least for the unicellular organism, much more fundamental. We know from precipitin reactions and other evidence that there exist chemical differences in the proteins of higher plants and animals, but these have been unheeded by the naturalist because he had more obvious characters to guide him in discriminating between species. But the bacteriologist, bereft of other guides, has been compelled to fall back on chemical differences where morphology has failed him. At first he did it almost blindly, not quite realising the true nature of the characters he was invoking. Only now do we begin to get a hint of what I believe to have formed a large part of the course of evolution within the morphological boundaries of bacterial genera—namely, that it has been a chemical rather than a structural one—a change not so much in the configuration of the organism as in that of the protein molecules which build it up. Such changes should be in every respect subject to the same laws as govern morphological ones. It must be a question of chemical adaptation of the organism to its environment and survival of the chemically fittest. And all that I have said in the earlier part of this address as to the rapidity and extent of variation amongst bacteria would apply quite well to chemical changes.

Nevertheless, the conception of chemical evolution does not give us any final guide in classifying bacteria into species. We might apply the term "species" rightly enough to the protein molecule as soon as we understand its chemical difference from another protein molecule. But just as in the building up of higher organisms many proteins are concerned, so, though perhaps in a lesser degree of complexity, must the bacterial body be built up of several kinds of protein in varying combination, some perhaps peculiar to the species, others common to many. Thus, probably, must we explain the phenomena of specific- and group-agglutination. I am led to imagine the Gärtner group of bacilli, for example, as composed of a series of forms differing from one another only in the relative proportions of their various component proteins, each having, perhaps, a certain number of protein molecules peculiar to itself. I am not helped by this notion in deciding as to whether they are different species or not, but I am helped in understanding why I am unable to come to a decision.

The conception of chemical differences between species is a relatively novel one, and although precipitin reactions are applied in distinguishing between the blood of one known animal and another, no one has yet dared to define species on chemical grounds alone. We do not know enough to enable us to do so. So I must end, with the confession that I do not know by what criteria we can judge of actual specificity amongst bacteria. I am disposed to believe that no standard exists by which we can determine specific limits such as are applicable to more highly organised creatures. Much, however, is gained if we fairly face this conclusion. Indeed, it may well be that the labile nature of bacteria renders them a promising field of study for the evolutionist, in which he may experiment at will with species in the making, instead of inferring his conclusions from types already fixed.

[2] Medical Record, August, 1913.

TWO YEARS' EXPERIENCE WITH SALVARSAN.

BY SIR MALCOLM MORRIS, K.C.V.O., F.R.C.S. EDIN.,
SURGEON FOR DISEASES OF THE SKIN, SEAMEN'S HOSPITAL, GREENWICH; CONSULTING SURGEON FOR DISEASES OF THE SKIN, ST. MARY'S HOSPITAL, LONDON;
AND
HENRY MACCORMAC, M.B. EDIN., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, MIDDLESEX HOSPITAL; ASSISTANT PHYSICIAN FOR DISEASES OF THE SKIN TO THE SEAMEN'S HOSPITAL, GREENWICH, AND THE MIDDLESEX HOSPITAL.

DURING the last two years, at the Seamen's Hospital, Greenwich, and in private practice, we have had a not inconsiderable experience of the use both of salvarsan and of neosalvarsan, the results of which may be worth relating, as bearing upon the comparative merits of these remedies, their curative powers, the propriety of giving few or many injections, the desirability of relying upon them alone or of reinforcing them with mercury, and the means of avoiding dangerous or disagreeable reactions. The total number of injections was 500, of which 350 were salvarsan and 150 neosalvarsan injections.

Analysis of Cases.

The great majority of the patients were males, and as

[1] An abstract of this paper was read before the combined Thirteenth and Twentieth Sections of the Seventeenth International Congress of Medicine.

between the primary, secondary, and tertiary stages there was a great preponderance of cases in the secondary stage. The precise proportions, in percentages, are as follows:—

Males.		*Females.*	
Primary	6·2 per cent.	Primary	0·8 per cent.
Secondary	57·7 ,,	Secondary	12·1 ,,
Tertiary (including parasyphilitic) ...	21·1 ,,	Tertiary (including parasyphilitic) ...	2·1 ,,
	85·0		15·0

In point of age the patients ranged from 17 to 73, but the majority of them were young adults. Three of them were pregnant women, who were respectively in the second, third, and six months of pregnancy, and in neither of these cases did the injection cause abortion.

Technique and Dosage.

The injections, both of salvarsan and of neosalvarsan, have invariably been given by the intravenous route. In most cases a two-way syringe has been employed, but as an alternative method the fluid may be allowed to run in by force of gravity. It is of great importance to use a sharp needle. If this precaution be neglected some difficulty may be experienced in penetrating the vein.

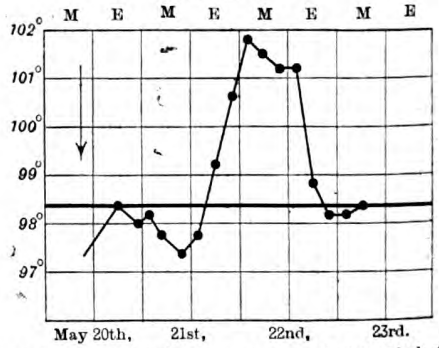
In *salvarsan* injections the salt has been dissolved in 40 c.c. of distilled water. Having been made alkaline with caustic soda, the solution, which should be quite clear, is added to physiological saline, a total volume of 300 c.c. of the mixture being used for 0·6 grm. of salvarsan, so that each 50 c.c. contains 0·1 grm. of the salt. In *neosalvarsan* injections 0·9 grm. of the salt, the equivalent of 0·6 grm. of salvarsan, is dissolved in 150 c.c. of distilled water, or in 150 c.c. of 0·4 per cent. of saline. The water must be cold, the mixture must not be shaken, and since neosalvarsan, being a neutral organic salt, is a much less stable preparation than salvarsan, it must be used immediately, otherwise it may acquire a dangerous degree of toxicity.

The number of injections in this series of cases has varied from one to seven, but in the great majority of instances it has not exceeded two. As a rule, we have used what may be considered the full dose of 0·6 grm. of salvarsan and 0·9 grm. of neosalvarsan.

As a control we have injected saline alone in cases of syphilis, and also the serum (blister fluid) of a treated patient, in both cases without definite result.

Reaction.

The series has been free from fatality, nor has there been any supervention of nerve deafness or of ocular trouble. The fever that often followed an injection in the early days of salvarsan administration was probably due in most cases not to the salvarsan itself but to the saline solution. The interesting series of experiments of E. C. Hort suggests that unless the water be freshly distilled and sterilised the typical reaction can be produced by the injection of saline alone. Indeed, we have found that if the water be freshly distilled (preferably in an all-glass apparatus) and the solutions be immediately autoclaved so as to be amicrobic, not only is there as a rule no resulting fever, but the fluid may be kept in sterile glass flasks for a month or six weeks and then used, no fever resulting. It is true that in some florid secondary cases there is a slight rise of temperature after the first injection, but this is due possibly to the destruction of an exceptionally large number of spirochætæ.



We must admit, however, that minor symptoms of reaction—headache, diarrhœa, and vomiting—are less easily avoided than fever, a fact which is probably to be explained by idiosyncrasy. We have found that the best way of averting such symptoms is to purge the patient the night before the injection, and to withhold food; but even so this form of reaction will sometimes arise.

In spite of all precautions, we have in a few instances found a second injection followed by a somewhat severe reaction. On the second or third day, in rare instances, a high fever has occurred lasting from 24 to 48 hours, the temperature then falling suddenly and leaving the patient quite well. That the reaction is not accounted for by any imperfect preparation of the distilled water is evident from

TABLE A.—*Deaths following a First Injection of Salvarsan.*

Reference.	Age.	Sex.	Condition.	Dose and method.	Death.	Notes.
Jorgensen.	40	M.	General paralysis.	0·5 grm., intravenous.	8 days after injection.	Said to be due to late absorption of arsenic.
Westphal.	33	M.	Tabes and syphilitic meningitis.	0·4 grm., intramuscular.	7 days after injection.	—
Martius.	56	F.	Aortic regurgitation.	0·5 grm., intramuscular.	17 days later.	Angina pectoris.
	39	M.	Cerebral syphilis.	0·5 grm., intravenous.	5 hours later.	—
	48	M.	Tabes.	0·6 grm., intramuscular.	Sudden death 6 days later.	Sclerosed coronary artery.
	44	M.	Syphilis and diabetes.	0·35 grm., intramuscular.	—	Diabetic coma.
	—	M.	Cerebral syphilis.	0·6 grm., intramuscular.	3 days later.	Heart failure.
	26	F.	Many abortions.	0·4 grm., intravenous.	3 days later.	Pulmonary embolism.
	40	M.	Paralysis.	0·5 grm., intramuscular.	5 days later.	Fatty heart.
	41	M.	General paralysis.	? dose.	—	Pneumonia.
	40	M.	Cerebral syphilis.	0·1 grm., intravenous.	Suddenly next day.	—
	40	M.	Aneurysm.	0·4 grm.	9 days later.	Pneumonia; infarction.
	?	?	Syphilitic aortitis.	—	—	Died during injection.
	44	M.	Paralysis.	0·5 grm.	5 weeks later.	Septic infection.
	—	M.	Moribund.	—	—	—
	60	M.	Old syphilis.	0·5 grm., intramuscular.	2 days later.	—
	35	M.	General paralysis.	0·5 grm., intravenous.	4 hours later.	Cerebral hæmorrhage
	—	—	Aortic regurgitation; tabes.	0·3 grm., intramuscular.	A few days later.	—
	28	F.	Laryngeal syphilis.	—	A few hours later.	—
	47	M.	Tabes, &c.	0·5 grm, intramuscular.	21 days later.	Aortitis.
Oltramore.	48	M.	Tertiary syphilis (meningitis, &c.).	0·6 grm., intravenous.	6 days later.	Cyanosis; coma; convulsions.

CHART 1.

Temperature chart showing fever (possibly of an anaphylactic nature) following a second injection of salvarsan, indicated by the arrow.

the fact that other injections given at the same time from a portion of the same fluid have been followed by no such phenomena. This fever is possibly of the nature of an anaphylactic reaction. (See Chart 1.) In three instances a second injection produced a reaction so violent as to give rise to considerable anxiety. It may be worth while to recite the details of these cases.

The first case was that of a male, aged 40, whose general state of health was good. He was in the tertiary stage with an ulcerated tongue. He had had an injection of 0·6 grm. of salvarsan seven months before. Within 15 minutes of the second injection, the dose being the same, the patient experienced severe thoracic pain, his face became so swollen that his eyes were scarcely visible, there was marked cyanosis, and for half an hour he seemed to be *in extremis*. Improvement then began, but he remained very collapsed for five hours. After that he gradually regained his normal condition.

In the second case the patient, a healthy male of 24, with secondary syphilis, had a second injection of salvarsan 14 days after the first, the dose on the first occasion being 0·6 grm. While the second injection was being given he suddenly became faint, cyanosed, and pulseless, and was then seized with epileptiform convulsions. By the evening, however, he had quite recovered.

In the third case, also, that of a male of 26, the disease was in the secondary stage. Two injections of 0·9 grm. of neosalvarsan were given with an interval of eight days. On the day after the second injection he became extremely ill, with hiccough, vomiting, and an almost imperceptible pulse, and remained in that condition for 24 hours, when he began slowly to recover. On the third day from the injection a jaundice commenced to develop, which by the fourth day had become generalised. Then an improvement began, but he remained seriously ill for some weeks.

TABLE B.—*Deaths following Second or Subsequent Injection of Salvarsan.* (All intravenous, except where otherwise stated.)

Reference.	Age.	Sex.	Condition.	Doses and interval between doses.	Death.	Notes.
Selenen.	50	M.	Ulcer of stomach (W +).	First = 0·5 grm. Second, 12 days later = 0·5 grm.	7 days after second injection.	(? Heart failure.)
Hirsch.	Young adult.	M.	Primary.	First = 0·5 grm. Second, 12 days later = 0·5 grm.	A few days after second injection.	Jaundice; convulsions.
	23	F.	Secondary.	First = 0·3 grm. Second = 0·4 grm., 36 days later.	2 months after second injection.	Jaundice; convulsions.
Hoffmann.	15	M.	,,	First = 0·3 grm. Second = 0·3 grm., 6 days later.	67 days after second injection.	Jaundice; coma (acute yellow atrophy). Second injection intramuscular.
Fischer.	40	M.	,,	First = 0·4 grm. Second = 0·4 grm., 40 days after first.	4 days after second injection.	Hæmorrhagic encephalitis.
Hammer.	Adult.	M.	Primary.	First = 0·6 grm. Second = 0·6 grm. Third = 0·6 grm. Fourth = 0·6 grm. (15 *months* after first.)	3 days after fourth injection.	Convulsions, &c. Was also given much Hg.
Balzer and Condat.	34	M.	Secondary.	First = 0·3 grm. Second = 0·3 grm., 1 week after first.	3 days after second injection.	Coma; convulsions.
Heyes.	25	M.	,,	First = 0·4 grm. Second = 0·3 grm., 18 days after first.	7 days after second injection.	Coma; jaundice.
Von Ofenheim	23	M.	,,	First = 0·6 grm. Second = 0·6 grm., 7 days after first.	3 days after second injection.	Coma; convulsions.
Traisfontaires.	24	F.	Secondary ?	First = 0·5 grm. Second = 0·5 grm., 7 days after first.	4 days after second injection.	—
Ravaut.	40	M.	Secondary (albuminuria).	First = 0·4 grm. Second = 0·7 grm., 7 days later.	19 days after second injection.	Kidney disease. Had had hectine previously. Second injection intramuscular.
	32	M.	Tertiary (cerebral syphilis, &c.).	First = 0·6 grm. Second = 0·6 grm., 7 days after first.	4 days after second injection.	Convulsions; coma; cirrhosi of liver, &c.
	45	M.	Tertiary and cancer.	First = 0·6 grm. Second = 0·6 grm., 7 days later.	15 days after second injection.	Acute cancer.
Caraven.	21	M.	Primary.	First = 0 6 grm. Second = 0·6 grm., 7 days later.	3 days after second injection.	Cyanosis; fever; coma.
Gaucher.	19	M.	Secondary.	First = 0·6 grm. Second = 0·6 grm., 4 days after first.	3 days after second injection.	Coma and convulsions.
Hallopeau.	35	M.	Tertiary.	First = 0·3 grm. Second = 0·4 grm., 6 days after first.	3 days after second injection.	Coma and convulsions.
Fischer.	40	M.	Secondary.	First = 0·4 grm. Second = 0·4 grm., 40 days after first.	4 days after second injection.	Cheyne-Stokes breathing; fever; hæmorrhagic encephalitis.
Levy.	41	M.	Primary.	First = 0·45 grm. neosalvarsan. Second = 0·6 grm. neosalvarsan, 7 days after first injection. Third = 0·6 grm. neosalvarsan, 3 weeks after first injection. Fourth = 0·9 grm. neosalvarsan, 10 days after third injection.	6 days after fourth injection fever commenced. Died 14 days after fourth injection.	An alcoholic; liver cells degenerate.

These cases show that, however much care be taken in administering the drugs, the injection may occasionally provoke a serious and even alarming reaction, and our experience is that this is more likely to occur with second than with first injections. Care must, however, be taken not to confuse between coincidence and consequence. In two cases acute otitis media followed an injection of neo-salvarsan; in a third an attack of acute appendicitis came on three days after a first injection of salvarsan. It seems to us not improbable that these phenomena were merely coincidental. In two cases a herpes zoster developed a few days before treatment began. Had this occurred shortly after the injection it might have been attributed to the arsenic.

Deaths from Salvarsan collected from the Literature.

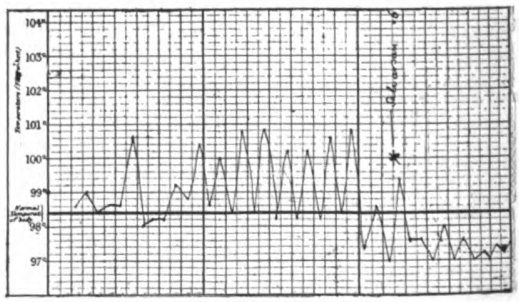
Before setting out the results of our experience we may call attention to cases in which the injection of salvarsan has been attended with fatal results. They may be divided into two main groups. First there are those in which such grave conditions as diabetes, aneurysm, aortitis, heart disease, cerebral disease, tabes, general paralysis, and cancer were present. In this group death has usually taken place after the first injection. It was so in the 21 cases included in Table A, and there is no difficulty in such cases in explaining the fatal result, which is no doubt due to the inability of the patient to tolerate the application of so powerful a remedy.

The second group of fatalities is less easy of explanation; it includes many cases of young adults affected with mild secondary syphilis, but otherwise healthy. In Table B will be found details of 18 cases belonging to this group.

It will be observed that in every one of these cases death has followed a second or subsequent injection. The frequency with which the unfavourable symptoms arose on the third day from the fatal injection is remarkable. If the table be examined it will be seen that the symptoms sometimes supervened so long after the first injection as to render extremely improbable the theory that they were provoked by an accumulation of arsenic. It is not easy, therefore, to see how the fatalities are to be accounted for except by assuming an anaphylactic reaction, the effect of the first injection, or the combined effect of two or more injections, having been to set up a condition of supersensitiveness, and the typical symptoms developing after a period of incubation.

There are no doubt some fatalities which do not fall into either of these two categories. Thus there are cases in which death has occurred during the injection, probably as the result of embolism or of some error of technique. We have not met with such cases in the literature, but we have heard of their occurrence.

General Results.



In all our primary cases the disease has been immediately arrested, and in none which we have been able to follow up have secondary symptoms developed, with the exception of sore throat. In secondary and tertiary cases the skin lesions, without a single exception, have rapidly disappeared. These results are extremely satisfactory, but we have no inclination to put the claims of salvarsan too high. The majority of our patients were sailors, whose cases it was impossible to follow up. Moreover, we have not felt ourselves justified in relying solely upon salvarsan, and we have therefore supplemented it with mercury wherever patients could be prevailed upon to take a course of that drug. Even so our series of cases has not been free from recrudescence. In a few instances the patients have returned after two or in some cases three injections, with a complete relapse. One case was peculiarly disappointing, for after having had three injections and been under observation for nine months with consistently negative Wassermann reactions the patient relapsed six months later and infected his wife.

Results in Secondary Cases.

In all these cases there has been rapid disappearance not only of cutaneous but also of mucous membrane lesions. The rash has quickly faded, but some pigmentation has usually persisted for a considerable time. The general condition also has greatly benefited, the appetite improving, and the patients putting on weight and gaining colour.

The effect of salvarsan in reducing the temperature in secondary cases is remarkable. When syphilitics are being treated as out-patients the fact that they are suffering from slight fever is apt to be overlooked. Sometimes the fever is more than slight, as in the case to which Chart 2 relates.

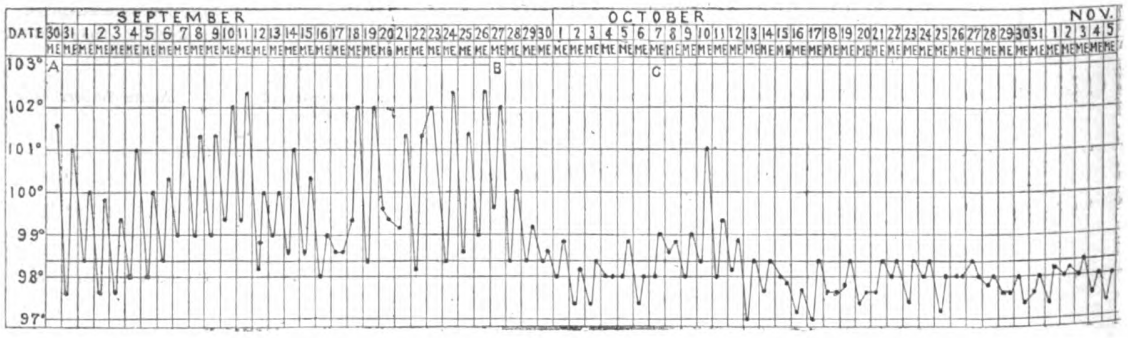


CHART 2.

Temperature chart showing effect of salvarsan on fever of secondary syphilis. The star indicates the date of injection.

The case was one of ordinary secondary syphilis, and the only unusual feature it presented was that the temperature on several days rose nearly to 101° F. The effect of salvarsan in quickly bringing it down to normal is shown by the chart.

CHART 3.

Temperature chart of patient with severe secondary syphilis showing effect of salvarsan. A, On admission; B, Salvarsan 0·6 grm. injected; C, Salvarsan 0·6 grm. injected.

A still more remarkable instance is that of which Chart 3 is the record. The patient was a young man aged 24 with secondary syphilis of a very severe type. His general condition was extremely grave; he was propped up in bed, pale, sweating, with rapid pulse and respiration. So ill was he that at first salvarsan was withheld, but as a last resource an injection was given, with a result almost astonishing in its rapidity and completeness. The temperature fell to normal, and the effect on his general condition was equally striking. Ten days later a second injection was given, and he then left the hospital apparently quite well. So desperate was his condition until salvarsan was employed that we have little doubt it saved his life.

The influence of salvarsan on the Wassermann reaction in our secondary cases is as remarkable as its effect upon the fever. If the test be applied from week to week a fall in the strength of the reaction is in many cases observed. Sometimes the diminution is gradual, and the reaction does not become negative until three or four injections have been given. In most cases, however, the reaction loses strength more rapidly, two injections sufficing to render it negative. Occasionally there is at first a slight increase in strength, followed by a more or less rapid decrease. It must be added, however, that the effect on the reaction varies a good deal, and in a small proportion of our cases, in spite of treatment, it has remained positive for as long as three months. In tertiary syphilis the reaction is much more difficult to influence.

Results in Tertiary Cases.

In this group, even in cases that had proved obdurate to mercury and iodide of potassium vigorously and perseveringly administered, we have not had a single failure where the integumentary system was attacked. Almost as much may be said of lesions of the tongue. Here, however, we have two disappointments to record. In one case the patient, a male between 45 and 50, who had received one injection of salvarsan, returned a week later for a second injection, when it was found that in the interval an active carcinoma had developed and that the submental glands had become the seat of metastases. In the other case, that of a man of 50 with severe lesions of the tongue, there was also nephritis, so that the dose of salvarsan was limited to 0·2 grm. Even this was borne so badly that no more salvarsan was given. The patient succumbed to carcinoma six months later. This perhaps should hardly be debited to salvarsan as a failure, the case being one in which the remedy could not be properly applied, and it was only resorted to because of the severity of the lingual lesions, which other treatment had proved powerless to influence.

Against these cases may be set one in which salvarsan acted with marked efficacy. The patient, a woman of 24, with syphilis contracted two years before, had had full doses of potassium iodide for a small ulcer on the left side of the tongue. Then for six months she had had a course of mercury by the intramuscular method. Under this treatment the ulcer had shown no regression whatever. Within a week of the injection of less than a full dose of salvarsan, 0·5 grm., it had completely healed, leaving only a small scar.

We have had excellent results also in the few cases of orchitis and tertiary gland enlargement treated with salvarsan. In one case of cerebral syphilis, in which the patient complained of severe vertigo and pains in the head and had had hemiplegia, all these troubles cleared up as the result of small doses of salvarsan, given in two courses, and the general health was greatly benefited. In tabes, apart from the cessation of lightning pains, we have found salvarsan of little service, and in syphilis of the nervous system generally our results have on the whole been disappointing.

It may be mentioned in passing that our experimental employment of salvarsan in non-specific conditions that respond more or less to arsenic, such as lichen planus and psoriasis, has yielded only negative results.

Salvarsan and Neosalvarsan.

As between the two preparations, our results incline us to give the preference to the earlier one. Neosalvasan is not only less stable than salvarsan, so that unless it be used at once its toxicity may be intensified to the danger point, but we have found it to be less rapid in its effects, lesions disappearing less readily under its influence, and the Wassermann reaction remaining positive longer.

Number of Injections.

In a very few instances we have given as many as seven injections, but the circumstances were quite exceptional, and experience and reflection combine to lead us to the conclusion that this potent drug should be used more cautiously and more sparingly than is advised by some authorities. The danger of establishing a condition of anaphylaxis should always be borne in mind, and it is not without serious significance that the fatalities in cases in which contra-indications were entirely absent followed not a first but a second or later injection. Moreover, as the result of a free use of salvarsan, the spirochæte may be rendered resistant towards arsenic. Ehrlich and his assistants have demonstrated that trypanosomes are capable of becoming resistant towards all the agents employed to effect their destruction. Thus, there were formed fuchsin-fast and arsenic-fast strains of trypanosomes, and in the same way the frequently repeated injection of salvarsan may result in the production of an arsenic-fast strain of spirochætæ. If we had to rely upon salvarsan alone we should be justified in taking these risks, but with mercury to fall back upon they ought, in our view, to be avoided.

Importance of Early Treatment.

Desirable as it is to secure the rapid disappearance of the secondary or tertiary phenomena, it is of still greater moment to abort syphilis in the first stage, so that it may never develop into a constitutional disease, or to arrest it at the very beginning of the secondary stage. Now that the presence of the spirochæta can be demonstrated with comparative ease in the primary sore it is no longer necessary to wait even for induration. Neisser's experiments with apes show that the virus has found its way to the internal organs within 16 days of infection, that is even before the appearance of the primary sore, and the generalisation of the disease appears to be complete, as a rule, by the time the chancre appears. The obvious inference is that whenever a suspicious sore comes under notice it should be examined for spirochætæ without delay, and that whenever a possibly syphilitic rash is observed the Wassermann test should be applied. If in either case the result is positive and no contraindications are present, an intravenous injection of salvarsan should be given, while in the former case the sore should, if possible, be excised or destroyed with the cautery. A mercurial course should at the same time, in our opinion, be begun. After a few days a second dose of salvarsan should be given, and if after another short interval the Wassermann reaction has not become negative, a third. In all cases the course of mercury should continue, with intermissions, for two years. In cases treated thus, the vast majority of the spirochætæ will as a rule be destroyed by the salvarsan, and the remainder disposed of by the mercury.

Is Salvarsan a Cure?

In connexion with a disease in which there may be recrudescence years after the disappearance of all symptoms, and in which the Wassermann reaction may return to the positive although there are no further clinical phenomena, the term "cure" must obviously be used with great caution. The most that we are able to say from our own experience is that in two of our cases treated with salvarsan alone the Wassermann reaction has remained negative after the lapse of a year. At the present time the only conclusive evidence of cure is reinfection, of which we have had no instance. Cases of reinfection have, however, been recorded by, among others, Colonel T. W. Gibbard, R.A.M.C., who last year reported five such cases in the Rochester Row series. In each instance the sore was on a fresh site and occurred within the incubation period from the date of exposure to infection, and though it is possible that the lesions were chancriform gummata, this is rendered very improbable by the large number of spirochætæ present in each lesion. But although salvarsan may in some cases abort the disease in the primary stage, and may effect a permanent cure in later stages, these results cannot be confidently counted upon, and prudence dictates that in every case this remedy should be supplemented by a course of mercury. On the other hand, that salvarsan has a more rapid and powerful effect upon the spirochæte than mercury seems to us indisputable. In some of our cases malignant and less severe types of syphilis that had proved absolutely resistant to mercury, or to mercury *plus* potassium iodide, have promptly yielded to salvarsan. With mercury alone, however administered, lesions are much more persistent, and in nearly all cases the Wassermann reaction remains positive during the first year and in about a third of the cases for over two years. The superior virtue of salvarsan is therefore demonstrable, and in every case in which it is not contraindicated it ought, in our opinion, to be administered as soon as the diagnosis is established.

AN ARTERIO-VENOUS ANEURYSM OF THE AXILLARY VESSELS OF 30 YEARS' DURATION.

BY SIR WILLIAM OSLER, BART., M.D., F.R.S.,
REGIUS PROFESSOR OF MEDICINE, UNIVERSITY OF OXFORD.

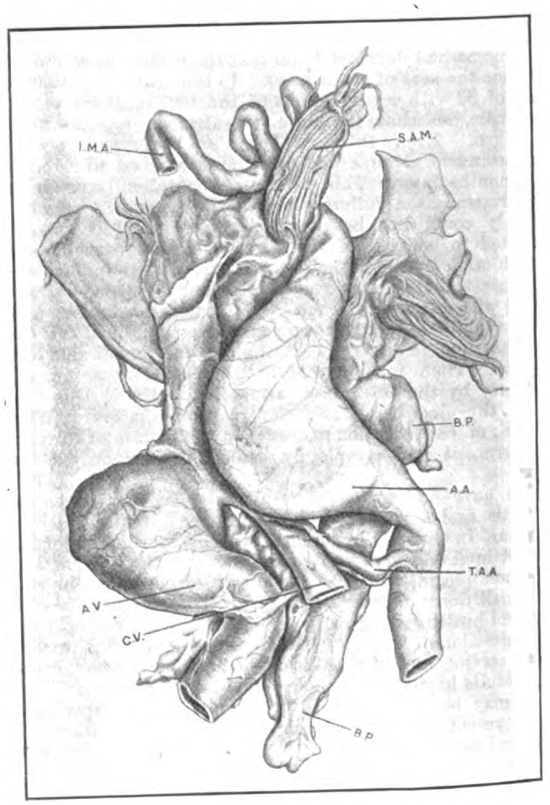
I HAVE been able to follow to the end this remarkable case, which I reported in 1893 in the "Annals of Surgery." My original notes are as follows:—

On Dec. 28th, 1888, I saw in Hamilton, Ont., with Dr. A. E. Malloch, a patient, aged 25, who presented the following condition: he is a strong, healthy young man, with a fresh complexion, well-developed muscles, and a well-shaped thorax.

Inspection.—The apex beat of the heart is in the fifth interspace inside the nipple line. There is a slight fulness beneath the outer half of the left infra-clavicular space, and pulsation is seen in this region; there is also slight, but not nearly such marked, subclavicular impulse on the right side. The carotids do not throb visibly, but on the left side above the clavicle there is fulness and a distinct impulse. The position and appearance of the left clavicle are normal. It is not elevated. There is perhaps slight fulness in the first intercostal space, near the sternum; there is no special prominence of the first rib or of the manubrium sterni.

Palpation.—The cardiac impulse at the apex has moderate force; there is no thrill. There is no impulse upon the sternum or beneath the inner half of the left clavicle. There is a very distinct impulse in the prominence above referred to in the outer half, upon the clavicle itself, and upon the infra-clavicular fulness. A continuous vibratory thrill is felt over the whole region of pulsation and the entire left side of the root of the neck. It is not felt on the right side, nor over the sternum, nor on the præcordia. There is no definite tumour to be felt either below or above the clavicle; the enlargements referred to are soft and yield readily to pressure. High up in the axilla there is a fulness in the course of the artery. To the touch it does not give the sensation of a distinct tumour; there is a remarkable continuous thrill in this region which is obliterated here and in the subclavian region when the axillary artery is compressed. The left arm looks normal, the veins are not distended, the finger-nails are neither blue nor incurved, and the tips are not clubbed. The pulse in the left radial is not so strong as in the right; there is no perceptible retardation.

Percussion.—The cardiac dulness is normal. Percussion over the manubrium and on the inner half of the infra-clavicular region is clear; the outer half is distinctly resonant.



Auscultation.—The heart sounds are clear at apex and base. There is no special accentuation of the aortic second sound; no murmur in the right carotid, or in the right subclavian arteries. Over the outer half of the left infra-clavicular area, on the corresponding portion of the clavicle, over the whole cervical triangle from the sterno-mastoid border to the attachment of the trapezius there is a loud continuous bruit. This murmur is also heard with great intensity in the axilla, down the inner surface of the arm, and on the front and back of the forearm. It is very loud and distinct in the palm of the hand and in the finger tips. In all of these regions the murmur resembles an intense *bruit de diable*, or a venous hum at the root of the neck. At one point only, just below the clavicle, there is a slight systolic intensification of the murmur. Posteriorly the bruit is heard in the subscapular space and feebly upon the scapula.

Subsequently when the patient came under my care in Philadelphia, he was seen by Professor Ashhurst, who noticed that pressure upon the axillary artery high up in the armpit caused complete disappearance of the thrill and the murmur in the clavicular region. The diagnosis of arterio-venous aneurysm was made.

The history of the patient is as follows. When 15 years of age, in running down a sloping grass plot he fell and forced a lead pencil, which was in his watch-pocket, into his armpit. When pulled out a gush of blood followed, which instantly ceased. Shortly after the arm began to swell, and became black and blue to the wrist. His physician kept him in bed for two days, and in the house for ten days with his arm in a sling. After this he had no special trouble, and has been accustomed to take a great deal of exercise, rowing in the summer and working hard in the gymnasium during the winter. He consulted Dr. Malloch for occasional pain in the lower portion of the chest and sleeplessness, but all this time he was keeping up his athletic sports, and the condition above described was only discovered accidentally by Dr. Malloch, who stripped him to examine for the cause of the pain. He has had no interference with the use of the arm, but considered himself in perfect health. Since the discovery of the condition he has been somewhat nervous and uneasy, and says that the pain has been aggravated.

The most careful examination of the axilla failed to discover the point at which the lead pencil entered. The patient was shown at a meeting of the College of Physicians in Philadelphia in January, 1889, and the general opinion of the surgeons present was that, as the condition had lasted for so many years, and had not seriously interfered with the use of the arm, nothing could be done. The friends of the patient became uneasy and were not satisfied with the opinions which had been given. He was sent to this country, and he sought advice in several quarters. In Dublin he very narrowly escaped operation, and even the day was set, but to use his own expression, he "escaped to London," where both Lord (then Sir Joseph) Lister and Sir W. Savory counselled non-interference, the former stating that life might not be curtailed at all by the affection, and that if at any time inconvenience arose the artery might be tied above and below the orifice of communication. The subsequent history of the case is of great interest.

I heard from the patient at intervals, usually to the effect that he was getting on very well; and Dr. Gustin, sen., of

S.A.M., Scalenus anticus muscle. A.A., Axillary artery. T.A.A., Thoracico-acromial artery. C.V., Cephalic vein. A.V., Axillary vein. I.M.A., Internal mammary artery. B.P., Brachial plexus.

St. Thomas, Ontario, an old friend, often reported on his condition. In 1900 I had a newspaper slip saying that the patient had served in the South African war, and had been invalided owing to an "aneurysm of the shoulder," and, moreover, that he received an allowance of £400 from a patriotic fund. I wrote to him, but could get no information about his life in South Africa. The other day, in reading Mr. G. H. Makins's "Surgical Experiences in South Africa," second edition, 1913, I recognised my old friend's case on p. 148. I copy here Mr. Makins's account.

During this he was seized with sudden pain in the left side of the head and neck, and in consequence invalided. No restriction in the movements of the upper extremity and no subcutaneous ecchymosis developed, but the patient was positive as to the tumour having greatly enlarged.

Four months later the condition was a little altered. A pulsating swelling 1½ inches broad existed along the line of the upper two-thirds of

the axillary artery and along the subclavian in the neck, rising some 1½ inches into the posterior triangle. Pulsation was visible. The murmur was audible when sitting beside the patient, and widely distributed over the whole chest, the neck, and upper extremity on auscultation. The pulse rate varied with the mental condition of the patient, which was excitable, between 96 and 120. There was neuralgic pain in the neck and scalp and down the distribution of the brachial plexus. The pupils were equal, but flushing of the face and profuse sweating followed any exertion. I concluded the tumour in this case to be mainly due to dilation of the trunk above the point of obstruction on account of its outline, the absence of any restriction of movement in the upper extremity, and the non-occurrence of subcutaneous ecchymosis at the time of the attack of severe pain. Difficulties arose as to undertaking any active form of treatment for this patient, which, to be satisfactory, needed an antecedent period of absolute rest, and he passed from my observation. I think, however, operation by ligature above and below the communication would have been possible. The case affords a good example of the course the condition may sometimes take if precaution is neglected.

On May 17th, 1909, when in Toronto, Dr. Gustin, jun., wrote saying that the patient had died, apparently from gradual heart failure. I wired at once that a necropsy should be performed, and Dr. Grey, of St. Thomas, kindly removed the heart and aorta, which he brought to Toronto for my inspection. Unfortunately, he did not know anything of the position of the aneurysm, and thought it was near the heart. The organ was uniformly and moderately hypertrophied; the valves were not involved and there was only moderate sclerosis of the aorta. Professor J. J. Mackenzie, of Toronto, who was greatly interested in the case, very kindly, on a later occasion, secured the vessels of the left arm, made the dissection, and had drawings made for me (see illustration). It will be seen that the axillary artery between the thoracico-acromial and the internal mammary is dilated and somewhat fusiform, with greatly thickened walls. The axillary vein is also greatly enlarged, with thickened walls. The most remarkable circumstance is that no communication could be found between the dilated vessels; whether or not a communication existed lower down (which is not likely) was not determined, as under the circumstances in which the specimen was procured it had to be rather roughly got out. Possibly the orifice of the communication gradually closed, though I have not met in the literature a case in which this is recorded.

I am greatly indebted to Dr. Gustin, of St. Thomas, and Professor Mackenzie for their kind help in following up this case.

Oxford.

THE VISCERAL COMPLICATIONS MET WITH IN HYSTERECTOMY FOR FIBROIDS

AND THE BEST METHODS OF DEALING WITH THEM.[1]

BY SIR JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

TWENTY years ago abdominal hysterectomy for fibroids was performed by clumsy methods and attended by a high mortality. In the Middlesex Hospital during 1892 the uterus was removed on account of fibroids three times; two of the patients died as a result of the operation, but in 1912 there were 71 abdominal hysterectomies for fibroids in the same hospital, and all the women recovered—a marvellous improvement in 20 years. To-day hysterectomy for fibroids is a common operation, with a mortality varying from 1 to 5 per cent. in the hospitals of London, general and special. I have chosen 1892 for comparison with 1912 because it is the year in which Baer of Philadelphia introduced the method now known as subtotal hysterectomy and inaugurated a new era in the surgery of the uterus. The technique of the operation varies very little with different surgeons, and I believe that the small mortality attending this operation can be further reduced. During the last ten years discussion has mainly centred around the subtotal and the total operation. I do not propose to discuss technique, but I believe some valuable information can be obtained by a consideration of the visceral complications associated with fibroids. So many of these tumours have been removed that there are surgeons who can count their hysterectomies in hundreds, and I believe that some useful facts can be collected if they would be willing to relate their experience in regard to the effects of fibroids on the circulatory system, the thyroid gland, the renal organs, and especially in relation to diabetes. These are conditions on the borderland of medicine and surgery. It will also be interesting to learn how surgeons deal with certain visceral lesions which occasionally complicate fibroids, such as cancer of the colon, injury of the ureters, and gall-stones.

[1] Introduction to a discussion at the Medical Society of London on Oct. 27th, 1913.

Cardiac Lesions.

Fibroids are often present in women suffering from chronic cardiac disease, and it has been maintained by several writers that uterine fibroids cause degenerative change in the muscular tissue of the heart. It is true that many patients with fibroids have valvular lesions, a consequence of rheumatic fever, and in many women who have been reduced to a condition of profound anæmia by a submucous fibroid the heart yields a loud murmur on auscultation. I have had careful observations made on the cardiac condition of women with fibroids, and there is nothing which can be described as peculiar to the influence of these tumours. It has been my practice for many years in selecting house surgeons to choose officers who have filled a resident appointment under a physician. All patients with fibroids, before being set down for operation, are the subjects of a careful medical examination.

On a dozen occasions I have removed the uterus containing large fibroids, although the heart has furnished murmurs, clearly due to valvular lesions, when an examination by a competent physician has shown that compensation has been satisfactory and that an operation would not be attended with unusual risks. Indeed, in some instances the removal of a uterus, big with fibroids, from a patient with valvular disease will relieve an embarrassed heart. For example, a stout woman aged 50 with a large ovarian cyst and a fibroid of the size of a football suffered from dyspnœa due to a dilated heart and myocarditis. The anæsthetist would not risk a general anæsthetic, but we felt that if the tumours could be removed great relief would follow. The tumours were removed under an intradural injection of novocaine. Convalescence was rapid, the cardiac symptoms disappeared, and the patient soon became robust, and has since led an active and useful life.

The heart is a very adaptable organ, and it is comprehensible, when we consider the size and vascularity of some fibroids, that the extra amount of work thrown upon it would lead to its enlargement. I believe that some cases of sudden death which occur within a few days of hysterectomy for fibroids happen in women the subjects of chronic, but unrecognised, disease of the heart. Some of these deaths are attributed to pulmonary embolism, but no death should be so assigned unless there has been a post-mortem examination and the embolus found. On this occasion I do not propose to discuss fatal post-operative pulmonary embolism, except to remind surgeons that recorded statistics indicate its occurrence in 1 per cent. of women who submit to abdominal hysterectomy for fibroids. I have recently published evidence which indicates in no uncertain way that it is often due to the exuberant use of buried sutures for closing the incision in the abdominal wall.

The Thyroid Gland.

From time immemorial it has been known that some mysterious relationship exists between the thyroid gland and the genital organs. No explanation has been found. The brilliant suggestion of Gaskell (in his fascinating account of "The Origin of Vertebrates") that the mammalian thyroid is the representative of the uterine glands of a palæostracan ancestor (of which the scorpion is a type) stimulates but fails to satisfy. To-day the matter is further complicated by the discovery of a relationship between the hypophysis and the genital glands on evidence at which even the most practical surgeon cannot scoff.

On three occasions I have removed a uterus containing fibroids from women who at the time of the operation possessed goitres. I have been surprised on seeing the patients six months after the hysterectomy to notice marked diminution in the size of the goitrous thyroids. In 1908 a spinster, aged 44, suffered from menorrhagia due to multiple fibroids, but she had exophthalmic goitre, and the thyroid was much enlarged. It occurred to me that as the removal of the uterus for fibroids causes a goitre to shrink such a

sequel might be expected if hysterectomy was performed on this patient. After careful consideration I removed the uterus with the ovaries and tubes by the subtotal method. The operation was performed at the Middlesex Hospital and lasted 12 minutes. Chloroform was used for the anæsthesia. Before operation the patient's temperature was 99° F., and the pulse-rate 130. 20 hours after the operation her temperature was 102° and the pulse rate 140 per minute; but the thyroid gland had markedly decreased in size and the eyeballs were less prominent. 48 hours after the operation she was in a desperate condition. The temperature was 104°, pulse rate 180 per minute, and the thyroid gland had further diminished in size. The patient died 56 hours after operation. A post-mortem examination was not permitted. This experience confirms the opinion that women with well-marked exophthalmic goitre are bad subjects for any operation.

Diabetes.

The presence of sugar in the urine is, as a rule, a contra-indication to hysterectomy for fibroids. All patients requiring hysterectomy who come under my care have their urine carefully examined for sugar. It is a serious responsibility to operate on a patient whose urine contains sugar, but the risk must be faced in exceptional cases.

A widow, aged 43, passed sugar in the urine to the extent of 5 grains per ounce. She suffered from menorrhagia, her menstrual periods lasting on an average ten days, the excessive bleeding depending on a large submucous fibroid. The patient wished to re-marry and was deterred from doing so, not by the glycosuria, but the menorrhagia. She wished to have the tumour removed and was willing to face the risks. I performed a subtotal hysterectomy. The operation was followed by a quick and uneventful convalescence. The patient married again, and was in good health three years after the operation.

The following case is more instructive. A married woman, aged 69, had a large uterine fibroid. There was free bleeding from the vagina at frequent but irregular intervals which led me to suspect that cancer existed in the body of the uterus as well as a fibroid. The patient was diabetic, the urine containing 10 grains of sugar per ounce. I performed subtotal hysterectomy in 1904. The uterus contained a large submucous fibroid and a cancerous mass of the size of a tennis ball. The patient recovered; she was alive and well in 1912—eight years after the operation.

I am sure, as a rule, it is a wise thing to abstain from performing hysterectomy on diabetics, especially young women. I have gathered from facts related to me by surgeons that such operations are attended with a high mortality. In some cases hysterectomy has been performed without the surgeon suspecting the presence of sugar in the urine until diuresis and the odour of the patient's breath or coma led to an examination of the urine.

Before leaving the subject of diabetes in relation to hysterectomy, there is one aspect of it which is worth consideration. A large amount of evidence has been accumulated which tends to show that there is some interaction between the hypophysis and the genital glands. In acromegalic women menstruation is suppressed, and in some of them the urine contains sugar. Experimental evidence has also been adduced which is supposed to prove that the hypophysis enlarges temporarily during pregnancy. Marek reported the following observation. A woman, aged 26, was in the eighth month of pregnancy when she noticed that her gloves and boots became too tight. Her fingers thickened and the rings on them had to be removed with a file. She became sleepy and thirsty; sugar appeared in the urine. Gradually she assumed the coarse skin, thick lips, and projecting lower jaw so characteristic of acromegaly. The child survived its birth and in a few months the signs of acromegaly in the mother disappeared.

A large submucous fibroid produces similar changes in the uterus to those set up by the growth of a fœtus. Glycosuria occurs with sufficient frequency, as a complication of normal pregnancy and of fibroids, to make it conceivable that the uterine changes incidental to the growth of the fibroid may influence the hypophysis and thus be indirectly responsible for the glycosuria.

Some years ago it was the fashion to tell a woman who wished to have her uterus removed for fibroids that after the operation the skin thickens and she would grow fat and coarse. Experience teaches that the reverse is true. Women with large submucous fibroids are more or less in a condition resembling chronic pregnancy. Such patients sometimes become gross and fat and acquire a thick skin like acromegalics, but after a successful hysterectomy these unpleasant conditions disappear, as in Marek's patient. We know nothing of the condition of the hypophysis in patients who have had the uterus removed for large fibroids. I hope pathologists who have an opportunity of inquiring into this matter will help us.

The Renal Function.

The close relationship of the uterus, bladder, and vesical segments of the ureters leads to many complications when the uterus is occupied by fibroids and the changes which follow in the bladder, ureters, and kidneys, if the tumour is of such a size and shape as to cause retention of urine, are well known. The urine of patients with a large cervical fibroid, or a fibroid of the body of the uterus impacted in the pelvis, often contains slight traces of albumin. This is not a contra-indication to operation, and the albumin quickly disappears after the tumour has been removed. Some years ago systematic examinations were made of urine drawn from patients under my care within the first 36 hours after pelvic operations, such as ovariotomy and hysterectomy, and it was found in nearly every case to contain the colon bacillus. I am unable to offer any explanation of its presence. This is worth mention, obstetric physicians are unable to make anything better than a guess as to the mode by which the urinary system is invaded by the colon bacillus in that troublesome condition known as pyelonephritis of pregnancy. Chronic urinary troubles of septic origin do occur in association with uterine fibroids, but I have never seen anything comparable to the acute suffering, which is sometimes seen in pregnant women, when the colon bacillus invades the kidneys and ureters. One of the most serious accidents that happens in the course of hysterectomy is an injury to both ureters. This is serious enough when the accident is detected in the course of the operation, but is more unfortunate if it remain undetected until the nurse draws attention to the emptiness of the patient's bladder. No reliable estimate of the frequency with which ureters are injured in the course of hysterectomy for fibroids is forthcoming. British surgical literature contains few references, but it is only necessary to turn over the pages of the *Zentralblatt für Gynaekologie* to be satisfied that they are often cut. At the present time, when a ureter is injured in the performance of abdominal hysterectomy the surgeon endeavours to anastomose the cut ends. Failing in this, he implants the proximal end in the bladder wall. Urologists do not approve of this; they insist that when a ureter is engrafted into the bladder it becomes sclerosed by chronic ureteritis, which narrows and finally obliterates its lumen. This sclerotic obliteration does not happen in every case. Lockyer, in removing a fibroid which burrowed between the layers of the broad ligament, wounded the bladder and divided the right ureter. He repaired the hole in the bladder and removed the kidney. During the 24 hours following the operation the bladder remained empty. Lockyer re-opened the abdomen and found the left ureter cut; he engrafted its proximal end into the bladder through the wound, which had been already sutured. Convalescence was retarded by a urinary fistula, but Lockyer's resourcefulness was rewarded, for the woman recovered and was in good health three years later.

Many years ago I was present at a hysterectomy when a gynæcologist cut 3 inches out of a ureter, mistaking it for an adhesion. He tied the proximal end of the cut ureter with a silk thread. The patient, a middle-aged woman, recovered without an untoward sign and remained well. This led me to take a special interest in this method of dealing with a cut ureter. In 1909 I expressed the opinion that it is possible and probable that a ureter has been tied in the course of a hysterectomy, and the patient has recovered without anyone having a suspicion that such an accident happened.

Dr. J. D. Barney collected and classified the reports of 62 cases in which the ureter was injured. Of these, 16 were bilateral and 46 unilateral. The majority of the accidents occurred in the course of hysterectomy. He notes that sudden occlusion of the ureter by a ligature often produces no symptoms: sometimes it is followed by pain and tenderness in the kidney which subside spontaneously. In some

instances the accident is followed by hydronephrosis and he reiterates the opinion, which I have already expressed, that there is strong probability that a ureter is often unconsciously tied in the course of hysterectomy. If gynæcologists would tell us how they treat cut ureters this discussion would be justified, for if it is only necessary to tie the proximal end of the cut ureter the way out of an embarrassing accident would be greatly simplified.

Fibroids and Cancer of the Colon.

Fortunately, uterine fibroids rarely contract adhesions to the intestines unless the uterus and Fallopian tubes have been the seat of infection, gonorrhœal or puerperal. It is unusual for the surgeon to be hampered with bowel complications when he undertakes hysterectomy for fibroids, but he may have to deal with cancer of the sigmoid flexure of the colon or the upper part of the rectum. It has happened to me on several occasions in the course of removing the uterus for fibroids to find cancer of the sigmoid flexure. After completing the hysterectomy I excised the cancer in the colon and joined the cut ends of the bowel by an end-to-end anastomosis.

In the case of a woman blanched from profuse and oft-repeated uterine bleeding, due to a cervical fibroid, I removed the uterus and its neck (total hysterectomy), but whilst adjusting the intestines preliminary to closing the incision detected a cancerous focus in the sigmoid flexure of the colon. The patient had sustained a serious operation, and in her weak condition I did not think it wise to excise the bowel. She made an excellent recovery and was kept under observation. Two months later I excised the growth and she recovered easily from the operation, and was alive and in good health two years later.

The growth of cancer in the colon is often slow and insidious, and there is a massive form of colic cancer which, during its symptomless stages, is indistinguishable, especially when the mass lies in contact with the uterus, from a subserous fibroid. The diagnostic signs are sometimes especially deceptive if there should at the same time be a few small hard fibroids in the uterus. Sometimes I have undertaken an abdominal operation hoping to find an impacted fibroid, but have found a hard cancerous growth in the sigmoid flexure impacted in the pelvis, and the operation has ended in colotomy. In happier cases I have started on the operation with strong suspicions that the patient had a malignant mass in the bowel, but found an impacted fibroid. It is a most evil combination when a fibroid of moderate size occupies the uterus and a massive cancer of the sigmoid flexure adheres to it. I am not alone in such experience; some of my gynæcological colleagues have occasionally stumbled on a cancerous pelvic colon in mistake for a fibroid and have assigned the patients to their surgical associate for the operation of resection.

Uterine Fibroids and Gall-stones.

Gall-stones are common in women; so are fibroids; and it sometimes happens that women come under observation with the two conditions giving so much trouble that the surgeon is puzzled to know which should be dealt with first. On three occasions I have removed a calculous gall-bladder in the course of hysterectomy for fibroids. In each instance the uterus was so large as to require for its removal an incision reaching nearly to the ensiform cartilage. In these circumstances the removal of the gall-bladder was a simple operation. In one instance the inflamed gall-bladder adhered to a large subserous fibroid. In two other instances of this combination I removed the gall-bladder six months after the hysterectomy. The only definite rule which I think can be laid down in the matter is this: If a woman deeply jaundiced in consequence of a stone impacted in the common duct also suffers from a uterine fibroid, which so troubles her as to make it desirable to remove the uterus, I should prefer to remove the stone from the common duct first because it is well known that cholæmia predisposes to hæmorrhage. Hysterectomy in a woman with persistent jaundice is an operation which would place her life in the gravest peril from post-operative bleeding.

The pelvic complications of uterine fibroids, such as ovarian cysts, pregnancy, pyosalpinx, inflamed appendix, and the like are so common and so well understood that they have no place in this discussion. We are anxious to obtain the experience of those who perform hysterectomy for fibroids, especially in relation to such complicating conditions as heart disease, goitre, diabetes, renal disease, and cancer of the intestine. Fatal accidents in technique (such as hæmorrhage and shock) occur occasionally like railway collisions and deaths from lightning, but post-operative deaths from heart disease, pulmonary embolism, and injuries to the ureters will be fewer if we profit by the experience of those who have faced these difficulties. In this way the risks of hysterectomy for fibroids, though small, will be reduced, and small as they are, I am sure we have not reached the irreducible minimum.

Brook-street, W.

A CASE OF PITUITARY TUMOUR AND SELLAR DECOMPRESSION.

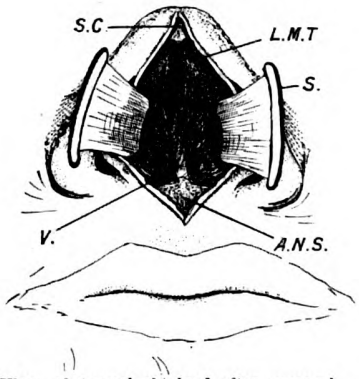
BY WILFRED HARRIS, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE;
AND
CECIL GRAHAM, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE EAR, NOSE, AND THROAT DEPARTMENT, ST. MARY'S HOSPITAL, W.

MANY cases have now been recorded by Hirsch, Cushing, and others in which decompression has been done by the intranasal route for the relief of the symptoms caused by pituitary tumour. An inspection of the inner surface of the base of a skull will make it at once evident that it would be quite impossible to remove any tumour through the floor of the sella turcica whose size exceeded that of a walnut on account of the lateral relationship of the internal carotid arteries as they approach the anterior clinoid processes; moreover, the size of the speculum which it is possible to introduce by means of this intranasal route would make the delivery of any larger tumour impossible except by means of scraping it away piecemeal with a sharp spoon. Owing to the hæmorrhage that is produced, and the impossibility of delimiting the extent of the growth when approached by this method, removal piecemeal is probably quite impracticable. Pituitary tumours probably rarely cause recognisable symptoms before they have reached a much larger size than that already suggested, and, indeed, the tumours that are found in this region at necropsies vary in size from that of a golf-ball to a tangerine orange, or even larger. The symptoms produced by a tumour of the pituitary body may be divided into three groups: (1) those produced by pressure upon neighbouring structures, particularly the optic chiasma and optic nerves; (2) those produced by general rise of intracranial pressure; and (3) those due to interference with the glandular function of the pituitary and its internal secretion.

Briefly, these symptoms may be as follows: **1.** Gradual failure of vision due to optic atrophy, usually of the primary type, but sometimes preceded by a slight degree of optic neuritis. In addition to general lowering of visual acuity, special characteristic phenomena are central scotomata, bitemporal hemianopia, and complete blindness in one eye, with persistence of the nasal field only in the remaining eye. Lateral pressure upon the cerebral peduncles is not usually sufficient to produce any definite paretic phenomena, though extensor plantar reflex may be found, and weakness of the legs and a tottery gait may be complained of. **2.** Intense optic neuritis from rise of general intracranial pressure is rarely seen, as also may be convulsions, hemiplegia, slow, irregular pulse, slow breathing, torpor, failing memory, &c. **3.** Acromegaly, gigantism, infantilism, and the various combinations described due to perverted secretion or failure of secretion of either the anterior or posterior lobe, or of both. The following case was of interest firstly in the making of the diagnosis, and especially from the extraordinary change and improvement resulting at first from the operation of sellar decompression.

A woman, aged 38, was brought to one of us (W. H.) on Nov. 11th, 1912, complaining of persistent headache, sleepiness and apathy, occasional tottery gait, and gradual failure of vision during the past 18 months. Three months previously she had had a fall, striking her left temple, and her symptoms had become rapidly worse since that time. On

examination her gait was seen to be weak and tottery, but there was no tremor of her limbs, nor any obvious ataxy. There was no localising weakness of any limb, and her sensation was everywhere normal. She was very sleepy and apathetic, and was said to have had delusions and occasional unconscious action of both bladder and bowel. The knee-jerks and the other deep reflexes were brisk and equal, but the left plantar reflex was of the extensor type, indicating probably some pressure on the pyramidal fibres in the right crus cerebri. Examination of the eyes showed no strabismus or nystagmus, but the right eye was completely blind, except for slight perception of light in the nasal field when tested with a bright light. There was good acuity of vision in the left eye with glasses, as she had 8 D. of hypermetropia, but the temporal field of the left eye was also quite blind, the only vision remaining to her being the nasal field of the left eye and a small area extending into the temporal field around the fixation point. The right disc was white and atrophic, while the left disc appeared quite normal. The right pupil did not react directly to light, though its consensual reaction when light was thrown upon the left eye was brisk, proving the blindness to be due to a lesion of the optic nerve and not of the visual centre. Her sense of smell and of taste was normal.



The diagnosis was fairly easy, the blindness of the right eye with optic atrophy, with temporal hemianopia of the left eye, strongly suggesting a lesion at the base of the brain, damaging the chiasma, and involving the right optic nerve, while the left extensor plantar reflex could be accounted for by the same lesion in the interpeduncular space, pressing against the right crus cerebri and thus affecting the pyramidal tract. Such a lesion being of slow growth, the blindness having been coming on for at least 18 months, was very probably a pituitary tumour, and the mental symptoms of apathy and sleepiness, incontinence of the sphincters, with absence of any hemiplegic symptoms or other cranial nerve palsies, fitted in well with the diagnosis of tumour of the pituitary, pressing upon the chiasma and right optic nerve. A skiagram of the skull taken in the lateral position confirmed this diagnosis fully, the sella turcica appearing much enlarged and boat-shaped, with the posterior clinoid processes sloping backwards. She was admitted next day into St. Mary's Hospital, and a test of her carbohydrate tolerance was then applied, 7½ ounces of glucose being given one day with her dinner without any trace of sugar appearing in the urine during the next 24 hours. She gradually became more and more torpid, and operation to relieve the increased intracranial pressure was

It represents the axis of the tunnel produced by the removal of structures between the incision superficially and the pituitary fossa, and it indicates the plane in which the section is made in Fig. 6.

decided on, preference being given to trephining through the base of the sphenoid into the sella turcica, after approaching by the intranasal route, rather than by lifting a bone flap in the temporal or parietal region, in order more directly to relieve the pressure of the growth in the pituitary fossa, rather than from any hope of being able to remove the tumour itself, as already explained. For the two or three days previous to the operation the drowsiness had increased almost to coma, with total incontinence of both sphincters and slowing of the respirations to 9 or 10 per minute.

Operation[1] was performed on Nov. 27th, 1912. Half an hour before operation morphine (¼ gr.) and atropine $\frac{1}{150}$ gr.) were injected subcutaneously. A quarter of an hour before operation both nasal fossæ were packed with gauze strips soaked in 1 in 1000 adrenalin containing 5 per cent. cocaine. Anæsthesia was induced by the intravenous injection of ether solution. The nasal vestibules, the upper lip, and neighbouring skin of the face were painted with tincture of iodine (B.P.) and a sterilised cloth was laid across the lower part of the face, a hole being cut in the cloth to admit of access to the nose. Illumination was obtained by means of a Nernst light reflected from a frontal mirror. One assistant was employed to keep the field of operation free from blood. The incision (Fig. 1), which was made through the skin, commenced at the tip of the nose and was carried to the upper lip, dividing in its course the columella and about ⅛ in. of the philtrum, keeping accurately in the middle line. The free edge of the septal cartilage was defined and the skin of the vestibule raised from each side of the septum. It was at this stage that the oozing of blood from minute points caused considerable delay in raising the vestibular skin, but the difficulty was overcome by assiduous mopping; and from this stage to the completion of the operation the hæmorrhage was insufficient to cause inconvenience, regular mopping being all that was necessary. The mucous membrane was easily raised from the sides of the septum and the elevation was carried back to within 1 in. of the posterior edge. A speculum with narrow 3 in. blades held the mucous flaps aside during the removal of that part of the septum which corresponded in antero-posterior depth with the raised mucous flaps, and in vertical depth with the skin incision, the tip of the nose being firmly upturned by the hand holding the speculum. The mucous membrane over the posterior edge and upper part of the vomer was raised by means of a dental "stopper" which terminates in a single corkscrew turn; the excursion of the instrument along the posterior edge of the vomer was controlled by the index finger of the left hand in the post-nasal space. Killian's long nasal speculum with flat blades, ⅓ in. by 4½ in., was then substituted for the smaller instrument, and the vomer was twisted from its attachment to the sphenoid by means of Luc's ethmoidal forceps. As it was found that the middle turbinals encroached upon the mucous membrane tunnel (Fig. 2) they were forcibly separated by means of a metal glove stretcher with screw attachment on the handles, the blades being inserted into the tunnel. The mucous membrane was then elevated from the anterior surface of the sphenoid so that the ostia of the sinuses were clearly brought into view. (Fig. 3.) The anterior wall and intersinous septum of the sphenoid were removed by means of small blunt hooks and Luc's ethmoidal forceps. The sinuses were symmetrical and there was no bulging to indicate the position of the pituitary fossa. The position of the pituitary fossa was found by taking a line which commences at the junction of the ala nasi and upper lip, and runs upwards and backwards towards the parietal eminence of the same side, and this line will be found to pass immediately beneath the lower and outer margin of the orbit. (Fig. 4.) A line commencing at the same spot and traversing the lowest part of the cavity of the orbit will be found to encroach upon the optic chiasma. The opening into the pituitary fossa was made by placing a long chisel parallel to the correct line, with the cutting edge against the roof of the sphenoidal sinus, and then cracking the bone by a few gentle taps of a hammer, a mastoid burr with a small head completing the stage. Immediately the bone was removed there was a rush of from 1 to 2 drachms of blood-stained fluid, and when the fluid was removed the dura mater was found to be lying against the opening. After enlarging the opening in the bone the dura mater was incised, and as this gave rise to brisk hæmorrhage on the two repeated attempts at exploration, the operation was concluded by swabbing out the area of operation with mops soaked in 1 in 4000 aqueous solution of mercury biniodide and then inserting a suture near each extremity of the skin incision and sealing the wound by collodion and cotton-wool.

FIG. 6.

I.T., Inferior turbinal. A.N.S., Anterior nasal spine. C., Cartilage. E., Ethmoid. I.S., Intersinous septum. P., Pituitary body. P.C.P., Posterior clinoid process.

The local after-treatment consisted of instillation of hydrogen peroxide into the nasal fossæ, followed by gentle irrigation with normal saline. Sixty grains of urotropine were given by the mouth upon the third and fourth days after operation respectively, then from the fifth to the seventeenth inclusive 45 grains were given daily.

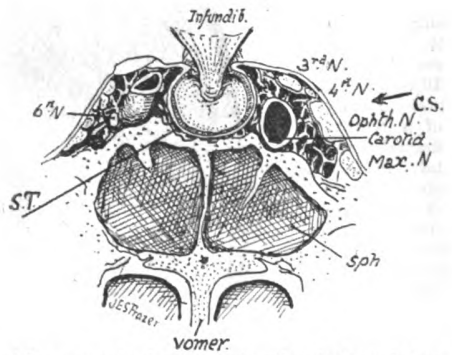
After a period of almost collapse, during which the jaws became fixed, the respirations being 24, the pulse 100, and

[1] Proceedings of the Royal Society of Medicine, vol. vi., No. 4.

the temperature 97° F., she recovered consciousness and spoke quite sensibly, and her reaction times were found to be much shortened. She was extremely thirsty, and passed five pints of urine in the 24 hours. The next day she became excitable and garrulous and sleepless, and on the following day she became suspicious, refused medicine, and had clearly lost touch with her surroundings. The thirst continued, and her mental peculiarities were evident for several days, especially in the evening; but by Dec. 3rd her mental condition was practically normal, though she was rather impatient unless attended to at once. There had been no incontinence since the operation, and she left the hospital apparently relieved of all her symptoms on Dec. 17th with the exception of visual defect, which was unchanged. She went down to stay with friends in the country, and for three weeks remained well, when drowsiness and headache began to return, increasing gradually until her readmission to St. Mary's on Jan. 22nd, when her state closely resembled that before the first operation on Nov. 27th. A noticeable point for the whole interval since the operation had been the continuance of great thirst and polyuria, in all probability due to the operation interfering with the inter-peduncular region of the base of the brain, as it is well-known that lesions in this neighbourhood, especially those of cerebral syphilis, often give rise to such polyuria.

A second operation was performed on Jan. 29th, 1913.[2] Because some difficulty in separating the muco-perichondral flaps made by the previous operation was anticipated, it was decided to approach the pituitary fossa by way of the left nasal fossa proper; therefore the ventricle of the left vestibule was laid open by an incision $\frac{1}{2}$ inch in length, which began at the opening of the naris and terminated at the tip of the nose. (Fig. 1.) Next the left middle turbinal was reduced in size by means of scissors and snare, and after a few drops of blood were removed on wood pledgets a vertical incision was made in the mucous membrane which had previously covered the front wall of the sphenoidal sinus. When the mucous membrane was separated laterally some difficulty was experienced in distinguishing the dura from the adjacent bone; after defining the opening into the fossa by means of a probe more bone was removed by means of an $\frac{1}{2}$ inch burr. Then a piece of the dura was removed by Luc's forceps and the fossa explored. A piece of growth was removed the size of half a walnut which appeared to be of a papillomatous nature. The patient bore the operation very well, and next day was well enough to be moved to another ward in the hospital, but the same night, 30 hours after operation, suddenly collapsed.

Post-mortem: Cerebral convolutions flattened. An encapsulated growth of the size of a small golf-ball was found in the position of the infundibulum in the floor of the third ventricle, distorting the optic tracts and raising the basal ganglia. There was a breach in the capsule of the growth where it lay over the pituitary fossa; the fossa contained a markedly compressed pituitary gland, but no more growth was found in the fossa. The entire floor of the fossa, which was very large, had been removed, the boundaries of the opening being the cavernous sinuses laterally, the olivary eminence anteriorly, and the dorsum sellæ posteriorly. There was no effusion of blood, nor was there any evidence of sepsis. Provisional diagnosis of perithelioma by microscopic examination (Dr. Spilsbury).



Remarks upon the Technique of the Operation.

1. *The incision.*—Being centrally placed it provides direct access to the line of approach to the pituitary fossa, and is a guide to maintaining the middle line during the stage of opening the floor of the fossa. Further, since the incision is the most constricted part of the tunnel which is eventually created, it is important that it should allow of an easy extension without producing any subsequent deformity or obvious scar.

2. *Exposure of the anterior surface of the sphenoid.*—Although the normal position of the middle turbinals does not form an obstacle to the removal of the nasal septum, the space between them is too narrow to allow a view of the sphenoidal ostia (Fig. 2 and Fig. 6). It is only possible to see a small area of the sphenoidal wall upon either side of the crest. The forcible separation of the bulging turbinals (Fig. 2) is easily accomplished by means of the metal "glove stretcher," and then the mucous membrane lying on the anterior wall of sphenoid is gently elevated by lateral movements of a flat-bladed elevator to give a perfect and simultaneous view of the ostia (Fig. 3). It is at this stage that an unavoidable communication is produced between the tunnel and the nasal fossa, because of the tearing of the mucous membrane from the margins of the ostia.

3. *Opening the floor of the pituitary fossa.*—The average distance that the sphenoidal ostia lie from the junction of vestibule and upper lip is 8·2 cm. in males and 7·6 cm. in females (Grünwald). The floor of the pituitary fossa lies at a distance of 2 cm. beyond the sphenoidal ostia. It is necessary, therefore, to have a probe marked at a distance of 10 cm. from its point to act as a control when attacking the area of bone which is taken to be the floor of the pituitary fossa. In the case reported above the sphenoidal intersinous septum was in the median plane, and it was found that the thickened ridge of bone formed at the junction of the intersinous septum and floor of pituitary fossa was more easily attacked by means of a few taps of a chisel than by a burr, since the burr slipped to one side or the other of the median plane. In a case with asymmetrical sinuses the burr would be the instrument of choice, since it requires little more than firm pressure to destroy the thin plate of bone which forms the floor of the pituitary fossa. The irregular disposition of the roof of the sphenoidal sinuses with the important overlying structures (Fig. 7) and the absence of any constant indication of

FIG. 7.

the position of the pituitary fossa make the removal of the floor of the fossa the most difficult step of the whole operation. In experimenting upon the cadaver it was found that a skewer placed with its point in the upper part of the pituitary fossa and its shank pressed against the floor of the vestibule (Fig. 5) lay in a plane corresponding to a line on the surface of the face which runs from the junction of the ala nasi and upper lip upwards and backwards to form a tangent with the lower and outer margin of the orbital cavity (Fig. 4). A section made in this plane is shown in Fig. 6. It was also found by slightly elevating the point of the skewer, so that the point now corresponded to the position of the optic chiasma (Fig. 5), that the instrument lay in a plane corresponding to a line which runs from the junction of the ala nasi and upper lip upwards and backwards to encroach upon the orbital cavity and so cutting a small segment of that cavity. The floor of the pituitary fossa, therefore, corresponds to that area of the roof of the sphenoidal sinuses, against which the chisel or burr impinges when it is placed in the plane indicated (Fig. 4) and also maintained strictly in the median sagittal plane. In determining the latter plane the alignment of the lower angle of the incision with the remains of the vomer may be used as a guide. If any doubt as to the correct elevation of the instrument were to exist in the mind of the surgeon, it would be advisable to place the instrument in a slightly lower plane than that which is indicated in Fig. 4, so that in the event of the instrument missing the fossa the presence of the cancellous tissue in the dorsum sellæ would be a comparatively safe guide as to the position of the point of the instrument.

The illustrations are from drawings by Mr. J. E. S. Frazer, F.R.C.S., Lecturer on Anatomy in St. Mary's Hospital Medical School.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE IN WHICH TUBERCULOSIS FOLLOWED INFECTION WITH SMEGMA BACILLUS.

By Stephen J. Maher, M.D.,
CHAIRMAN OF THE STATE TUBERCULOSIS COMMISSION, CONNECTICUT, U.S.A.

A previously healthy painter at work in a small swinging cradle high on the side of a building had the fold of his scrotum caught in a crease of his clothing in such a way as to cause severe pain. He was almost through with his day's work, and hampered as he was with paint-pots and brushes and the riskiness of his position, there would be difficulty and danger in attempting to obtain immediate relief. He bore with the distress of the clothes "bite" for longer than was wise. When his fellow painters lowered him to the ground the injured spot was red and sensitive, but he got considerable relief from bathing the parts. A few days later it was still sore. He visited a medical man who assured him that it was a trifling matter and gave him a soothing wash. A suspensory bandage helped for a few days, but there was soon evidence of abscess formation and the medical attendant aspirated nearly an ounce of creamy pus.

This pus was sown thick with what seemed to be pure smegma bacilli. They were short and straight, and although they retained the fuchsin after washing with Gabbett stain they were readily decolourised with acid alcohol. In the hope of getting a pure culture of smegma bacilli plants were made from this pus on a dozen kinds of media at various temperatures. In some of the tubes a faint streptococcus grew. In others there was no growth, and with a sense of disappointment I put the baskets back in the thermostat and did not look at the cultures again for a month. Then it was found that on the glycerine broth potato there had developed a few crumbs of bacterial growth, and these were composed of perfect tubercle bacilli. This surprising discovery was reported to the medical man in charge of the case. He said he could not understand it, because the man was now entirely well except for a tiny sinus at the point of aspiration, and the man certainly had no tuberculosis anywhere else in the body. Nevertheless, I subcultured the growths on the glycerine broth tubes and injected them into guinea-pigs. The guinea-pigs died from tuberculosis, as did a second series injected with the bacilli isolated from the first series. Still, at this time the patient was apparently in perfect health. His medical attendant still scouted the suggestion that there was any danger of tuberculosis in the case. Six months later, however, the patient suddenly developed symptoms of acute tuberculosis in both lungs, and in less than six months was dead.

Connecticut, U.S.A.

NOTE ON OZONE IN THE TREATMENT OF DYSENTERY.

By Professor Dr. Frank M. Lessing.

Having a case of severe dysentery in which the ipecacuanha and opium treatment failed to keep the diarrhœa in check, and in which the intestinal canal was becoming very excoriated, I decided to try the effect of ozone, the powerful action of which on cholera and typhoid bacteria is, of course, well known. Mr. Noël E. Dufty, engineer in chief of the A.E.G. Bangkok Branch, kindly placed at my disposal a small water ozoniser of the Otto type and an air ozoniser of the Dr. Franz Fischer's Nernst lamp type. The ipecacuanha and emetine hydrochloride treatment was continued and the lower intestinal canal was gently washed out with ozonised water from time to time, and ozonised water was freely drunk by the patient. The air of the sick room was also kept slightly ozonised with a view to reinforcing the antiseptic action. The improvement which followed was most marked. Dysentery speedily abated and the subsequent healing of the ulceration was also very rapid.

I venture to suggest that ozone may with great advantage be used in similar cases.

Congenital Syphilis of Liver Simulating Banti's Disease.—The Presence of a form of Streptothrix in Cases of Splenic Enlargement.—Chronic Recurrent Diarrhœa in Childhood.

A meeting of this section was held on Oct. 28th, Dr. Samuel West, the President, being in the chair.

Sir William Osler read a short paper on a case of Congenital Syphilis of the Liver with the Picture of Banti's Disease. He said that from the many kinds of splenic enlargement it was generally agreed that a definite entity could be separated with the following features: (1) Splenomegaly, which might persist without symptoms for many years; (2) progressive anæmia; and (3) cirrhosis of the liver and ascites. Removal of the spleen led to a cure in such cases, and this was the best evidence that in this disease the spleen was primarily at fault. He could recall three cases in which splenectomy had been performed; one was alive and well 14 years afterwards, one seven years, and one five years afterwards. In a considerable percentage removal of the spleen was followed by a permanent cure. He favoured the name "Banti's disease" as the best to designate this particular group of cases. The object of his paper was to call attention to a form of syphilis of the liver in which the association of splenomegaly with anæmia would suggest the diagnosis of Banti's disease, and he recorded an instance of this condition where, from the high leucocyte count, the blood picture might lead to the diagnosis of leukæmia. A similar case had been described from the clinic of von Jaksch, in which also lymphæmia was present. The paper was based on the case of a boy aged 11 who had been under his observation for from six to seven years. At first there was merely splenomegaly; two years later there were evident signs of syphilis, with enlargement of the liver and slight jaundice. The spleen was very large, occupying practically the whole of the left side of the abdomen. A smooth tumour, clearly an enlarged part of the right lobe of the liver, could be felt under the costal margin. Later the patient developed ascites, hæmatemesis, melæna, and marked anæmia, and died. The condition of the liver, post mortem, was remarkable. The left lobe had almost disappeared, and the organ showed a multilobular cirrhosis. The projecting part which had formed the tumour was a large portion of normal liver tissue, possibly due to regeneration. In two places small gummata were seen. The Wassermann reaction had been negative. He believed that such cases were more numerous than was generally supposed. It was for this reason, and because syphilitic cirrhosis of the liver was usually not diagnosed and might closely simulate the picture of Banti's disease, that he recorded this case.—Dr. W. Essex Wynter described a case of a patient in which the diagnosis of Banti's disease had been made. Post mortem, cirrhosis, due to acquired syphilis, had been found.—Dr. F. Parkes Weber emphasised the importance of fever in the diagnosis of obscure syphilitic lesions. The temperature chart in such cases might suggest tuberculosis, septicæmia—such as malignant endocarditis—or even typhoid fever.—Dr. Robert Hutchison thought that the clinical picture described by Sir William Osler was not infrequent in syphilis in children. There were also other cases in which syphilis played no part. It might also be simulated by metasplenomegalic cirrhosis.

Dr. A. G. Gibson read a paper on the Occurrence of Streptothrix in Enlargement of the Spleen. He thought that there was evidence that Banti's disease was due to infection, because it was cured by removal of the spleen, reacted satisfactorily to treatment by salvarsan, and bore a

resemblance to syphilitic cirrhosis, as Sir William Osler had just pointed out. He exhibited the spleen of a fatal case. The organ showed general fibrosis; the surface was greyish pink, and dotted throughout it were small areas of pigment. Microscopically these areas showed about the splenic veins masses of black staining material which consisted of segmenting threads. After careful examination he thought that there was no doubt that these constituted a growth of streptothrix. He had searched through the specimens of spleens at the Radcliffe Infirmary and had found three other examples of the condition. Another spleen, also exhibited, which had been removed by an operation, showed no excessive fibrosis, but was highly cellular, and there were many red blood cells between the trabeculæ, forming paler areas. In these pale areas numerous networks of fibrils were seen, which he also considered to be parasitic. In another tuberculous case the same appearances were found in the spleen, and the parasites were also seen in one cavity in the lung. He had been unable to obtain cultures of these organisms. He suggested that the appearances in the spleens examined were due to a streptothrix invasion, but did not go so far as to infer that all cases of Banti's disease were so produced. These parasites had been found in five out of 100 spleens which he had examined.—Sir WILLIAM OSLER agreed as to the parasitic nature of the foci, but thought that the relation which they bore to the disease was uncertain.

Dr. F. J. POYNTON, Dr. R. R. ARMSTRONG, and Dr. D. N. NABARRO communicated a paper entitled "A Contribution to the Study of a Group of Cases of Chronic Recurrent Diarrhœa in Childhood." The basis of this study was a fatal example with a detailed necropsy and pathological and bacteriological investigations. The patient, a boy, who at the time of death was 9 years old, had been under observation for four years. His first attack of diarrhœa had occurred at 12 months, and lasted eight months. While under observation between 5 and 9 years he had repeated attacks brought on by the least indiscretion in diet, for which he was admitted with such various diagnoses as abdominal tuberculosis, dilated colon, and cœliac disease. The motions were sometimes green, occasionally blood-stained, sometimes brown and very foul, or, again, white and creamy in consistence. Vomiting occurred, but was less prominent. Emaciation was extreme. Some fever was often present, but was never a striking phenomenon. The liver was enlarged, and this increased in the last stages of the illness. Appendicostomy produced some improvement for a short time, but death occurred with symptoms of peritonism for which no explanation was afforded after death. The necropsy showed the absence of tuberculosis and the presence of chronic inflammatory changes with thickening of practically the entire length of the alimentary canal from the stomach to the rectum. The nature of these changes were illustrated by microscopic sections and drawings. The liver was in a condition of the most extreme fatty change. The pancreas showed some interlobular fibrosis. There was no evidence in the body of tuberculosis. A bacillus corresponding in character and reactions to the bacillus dysenteriæ of Flexner was cultivated after death from the intestinal wall, together with some Gram-positive bacilli. Nine other cases were recorded illustrating various phases of these recurrent illnesses and exemplifying such striking features of the condition as infantilism, anasarca, cœliac symptoms, neuritis, dilatation of the colon, tetany, and arthritic changes. None of these cases was fatal, and the only case in which the B. dysenteriæ had been isolated was the fatal one. These data led to a consideration of these illnesses with particular reference to the condition first described by Dr. Gee as cœliac disease, later by Dr. Cheadle as acholia, and later again by Herter in his monograph upon the bacteriology of the alimentary flora in intestinal infantilism. It was suggested that the cœliac symptoms marked but a phase in the history of various abdominal affections rather than constituting a disease itself. Thus in the cases recorded in the paper, the writers had noticed that cœliac symptoms might only occur at times during the illnesses which themselves had probably originated from some infection. Were these cœliac symptoms then the result of the action of peculiar poisons the result of the infection, damaging, for example, the liver in some special way? Were they again partly the result of an unsuitable diet or of the peculiar bacterial flora in the alimentary canal as Herter had suggested? Attention was particularly directed to the extraordinary difficulty there was in feeding these children, and concrete examples were given in illustration. It seemed almost impossible to ascertain, except by bitter experience, the particular diet that would suit any particular case. Fats in their experience had proved the most difficult of assimilation. Herter laid stress on carbohydrates, and every kind of food element had at one time or another been apparently unsuitable. They believed that some of the cases described as Hirschsprung's disease were the result of these attacks in very early life, and gave an example in point. In such cases one section of the bowel was more damaged than the other (usually the large bowel), and became permanently toneless and dilated. The great difficulty in diagnosis was the exclusion of abdominal tuberculosis. They had found that these children might on more than one occasion be reduced by an exacerbation of their complaint to the last stages of inanition and weakness and yet recover. Such a grave condition in abdominal tuberculosis with no definite evidence of tuberculous disease would point to the gravest ulceration of the bowel, from which recovery on more than one occasion would seem most unlikely. This disease appeared in a considerable number of cases to abate in severity between five and seven years, although it might persist to adult life and produce remarkable infantilism.

MEDICAL SOCIETY OF LONDON.

The Visceral Complications met with in Hysterectomy for Fibroids.

A MEETING of this society was held on Oct. 27th, Sir DAVID FERRIER, the President, being in the chair.

Sir JOHN BLAND-SUTTON introduced a discussion on the Visceral Complications met with in Hysterectomy for Fibroids, and the Best Methods of Dealing with Them. His contribution will be found in our present issue, p. 1249. The object of the discussion was to obtain observations of physicians, surgeons, and gynæcologists concerning the effects of uterine fibroids on the heart and the thyroid gland, and in relation to diabetes. Also to obtain the opinion of surgeons in regard to such visceral complications of fibroids as cancer of the colon and gall-stones, and the safest method of dealing with injuries of the ureters.

Dr. A. E. GILES, speaking from experience obtained from over 500 cases of hysterectomy for fibroids, said that the heart complications were chiefly those of anæmia and myocardial weakness. He thought there was no connexion between fibroids and valvular disease. When heart weakness was present there was no very great risk in the operation itself, the risk being greater a little later on. He thought that such a patient should remain recumbent longer than was necessary in most other cases. He had not met with glycosuria as frequently as had Sir John Bland-Sutton and could only recall two cases with marked glycosuria, and one with diabetes. In the two cases of glycosuria the sugar disappeared from the urine after hysterectomy; in the diabetic patient coma supervened. He had encountered three cases in which carcinoma of the colon was diagnosed at the time of operation, and in none of them was resection performed then. One afterwards developed intestinal obstruction which necessitated colotomy; the other two patients were still alive four and seven years respectively after the operation. The diagnosis was therefore questionable in those two cases. He had not seen pulmonary embolism after hysterectomy for fibroids. Speaking of injuries of the bladder and ureter, he said that in three cases he had cut into the bladder. In one of these carcinoma was present, and the bladder had to be incised to remove the growth. He sewed up the site of the operation with silk in two cases, and a calculus developed around the stitches in each. The ureter was severed in two cases; in one he implanted the proximal end of the ureter into the bladder. Six months later there was a recurrence of carcinoma at the site of union of the ureter with the bladder. In the other case he anastomosed the cut ends of the ureter, but he had no means of judging of the result, as the patient died suddenly on the night following the operation.

Mr. DOUGLAS DREW recounted the history of a case of mitral stenosis with a large fibroid in which the uterus

weighed 15 lb. Before the operation the pulse ranged between 130 and 140, but directly after it fell to between 80 and 90. He also spoke of a case in which the thyroid was enlarged at the time of hysterectomy. The patient returned six and a half months later with a rapid pulse, proptosis, and great enlargement of the thyroid gland. In that case the thyroid had enlarged rapidly after the operation. He had experience of two cases of injury to the ureter. In one he fixed the ureter into the bladder and no trouble ensued; in the other he ligatured the proximal end of the ureter, and in that case normal convalescence occurred also.

Mr. HERBERT F. WATERHOUSE said that he would estimate the mortality from pulmonary embolism after hysterectomy at 2 per cent., and that it usually occurred at about the eighth, ninth, or tenth day after the operation. He differed from Sir John Bland-Sutton as to its cause, believing it to be due to overuse of large retractors, such as those of Doyen, and not to undue use of deep sutures. He thought that cardio-vascular symptoms and symptoms of thyroid activity were more frequent than is usually understood, and that they were toxic in origin, a poison from the degenerated fibroid causing, in his opinion, the myocardial degeneration and hyperthyroidism. He spoke of a case in which the symptoms of exophthalmic goitre disappeared almost entirely after the removal of a degenerating fibroid. He had not met with glycosuria, but thought that a diminution in the amount of urea was not infrequent. Albuminuria and œdema of the legs not due to pressure also occurred. These renal symptoms cleared up if the fibroid was removed. Injury to the ureter should never occur. It might be avoided if the operator took care to know the situation of the ureter from the pelvic brim to the bladder, even if this necessitated dissecting it out.

Dr. C. HUBERT ROBERTS said that he had injured the ureter on four occasions. In one a fistula persisted. In the second he ligatured the upper end and no ill effects followed. In the third there was a large cervical fibroid; in this case he implanted the ureter into the bladder, and the patient made a good recovery. In the fourth there was a large subperitoneal fibroid; a fistula followed, and ultimately the kidney was removed. He favoured implantation of the ureter into the bladder where it was possible. He did not think that pulmonary embolism often occurred. He had observed one case in which a goitre seemed to have improved after the fibroid was removed.

Mr. HERBERT PATERSON disagreed with the view that the use of buried sutures caused pulmonary embolism. He recalled a case of exophthalmic goitre which was associated with a degenerating fibroid and pyosalpinx, and in which the goitre improved after operation. He had operated upon three cases in which carcinoma of the colon complicated fibroids. He had removed the carcinoma and postponed dealing with the fibroids till occasion should arise. Such occasion had never followed. Under such circumstances he thought it was advisable to deal primarily with the cancer. He had only knowingly injured the ureter once. In that case he had tied both ends, and the patient recovered and had kept well ever since. Judging from experimental observations, the result of tying the proximal end of the ureter would be atrophy of the kidney.

Mr. A. E. JOHNSON thought that if the ureter was damaged the proper treatment was to engraft it into the bladder, and if subsequently contraction arose to open the bladder and improve the graft.

Dr. R. A. GIBBONS said he had operated upon a patient who had uterine fibroids and Graves's disease and who died from acute thyroidism. He had come to the conclusion that in such cases it was better not to operate unless the tumour actually threatened life. He agreed that the ureter was more often divided than is usually thought. As a rule, if the upper end was tied no untoward event followed. Before removing the kidney it was important that a cystoscopic examination should be done to determine whether the other kidney was active.

Dr. M. HANDFIELD-JONES emphasised the analogy between pregnancy and large fibroids, in both of which very large dilated veins occurred and pulmonary embolism was to be feared. He thought it more likely that pulmonary embolism was due to thrombosis in these large veins, than in small veins as the result of deep sutures.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Oct. 17th, Mr. A. Ernest Maylard, the President, being in the chair.—Dr. John M. Cowan, in giving a lantern demonstration on Auricular Flutter, reviewed briefly the literature on the subject. McWilliam in 1887 showed that the application of an electrical stimulus to the auricle produced a premature systole starting at the point of stimulation. Faradisation of the auricles "sets the auricles into a rapid flutter, the rapidity of which largely depends upon the excitability of the auricular tissue and the strength of current employed. The movements are regular; they seem to consist of a series of contractions originating in the stimulated area and thence spreading over the rest of the tissue. The movement does not show any sign of incoördination; it looks like a rapid series of contraction waves passing over the auricular walls," and thus differed from auricular fibrillation, in which the auricular contractions were incoördinate, much more frequent (500–600), and irregular. In 1905 Gibson and Ritchie reported a case, with polygraph tracings, of full heart block, in which, with auricular contractions numbering 246–300, the ventricular beats numbered only 30; and in 1906 a similar case. Morrison, Hertz, and Goodhart also published similar tracings. In 1910 Jolly and Ritchie commenced investigations with the electrical polygraph and, independently of others, isolated auricular fibrillation. They also examined the 1905 case of rapid auricular action, and found that the auricular waves were regular, numbering about 300, and diphasic. They suggested that this might be the same as McWilliam's auricular flutter. Further observations by Ritchie, Lewis, and others seemed to have established the identity of a new rhythm, and one that is not at all uncommon. Thirty cases had been published, and Dr. Cowan had found eight cases in his own collection, with polygraph tracings, and many more in which its occurrence seemed probable. A series of tracings illustrative of various types of auricular flutter was demonstrated.—Dr. Leonard Findlay read a paper on the Intestine as a Pathway of Infection to the Tubercle Bacillus, with special Reference to the Part Played by Enteritis. After a review of the experimental work already done on the subject, which showed marked differences in the results obtained, Dr. Findlay detailed a series of experiments which he had made with improved technique. The *causa morbi* in the form of culture of the bacillus was suspended in oil and placed in a gelatin capsule, which was slipped just within the nozzle of a stomach-tube and ejected by forcing a stream of water through it after its passage into the stomach. It had been previously found that the introduction of an emulsion of the bacilli per the stomach-tube almost invariably gave rise to insufflation tuberculosis, and any abdominal operation for its introduction direct into the stomach or intestine allowed of infection of the peritoneum. The experiments included the following: (*a*) A series of 12 healthy rabbits were fed as above described with bovine tubercle bacilli and killed after periods varying from 7 to 10 days later. In two of these tubercle bacilli were found in the mesenteric glands. (*b*) Five rabbits, which had previously suffered from diarrhœa, induced by the administration of an infusion of senna and gamboge, were killed six to eight days after the ingestion of the organisms. One animal showed tubercle bacilli in the mesenteric glands. (*c*) A series of healthy animals were similarly fed on bovine tubercle bacilli and allowed to live for prolonged periods. All that survived at least 50 days showed tuberculous lesions, which were situated invariably in the appendix and adenoid patch at the ileo-cæcal valve, and less frequently in the mesenteric glands. Only those animals which survived 70 days showed also lesions in the lungs. (*d*) In a similar series of long-period experiments in which the rabbits had previously suffered from enteritis caused by senna and gamboge, tuberculous lesions developed as early as 19 days, and were found in all that survived at least 30 days. The lesions were similarly distributed, but were much more extensive and more frequently generalised. (*e*) Eighteen healthy rabbits were fed on tuberculous sputum and on emulsion of human tubercle bacilli and allowed to live for long periods. Among these tubercle bacilli were present in the mesenteric glands in one case, in the lungs and at the ileo-cæcal valve in one case, and in the lungs alone in one case. (*f*) A series of five rabbits which had previously suffered from diarrhœa were similarly fed, and were killed at periods varying from 36 to

63 days after the ingestion of the human bacilli. All but one presented lesions in the appendix, in the adenoid patch at the ileo-cæcal valve and in the mesenteric glands. The conclusions drawn were as follows: 1. Healthy rabbits can be infected by the ingestion of large amounts of bovine tubercle bacilli. 2. The bacilli can pass through the apparently intact mucous membrane and reach the mesenteric glands within a period of six days; this, however, does not frequently happen. 3. When infection occurs the intestine is invariably the seat of lesions, and thus tuberculosis of any organ, other than the intestine, is always a secondary infection when the bacilli have entered by the intestinal route. 4. Catarrh of the intestine does not favour the passage of the tubercle bacilli through the wall, but allows of a more constant and also of an earlier and more widespread infection of the bowel, and in this way facilitates dissemination. 5. Healthy rabbits can be infected by the ingestion of large amounts of the human tubercle bacillus. 6. Rabbits just recovered from intestinal catarrh develop tuberculosis more easily and much sooner after the ingestion of human tubercle bacilli. 7. With the human type of organism a local lesion, though always present, may be slight in comparison with the diseased foci in the mesenteric glands and lungs. 8. In digestion experiments with the human type of bacillus it would seem possible for the local intestinal lesion to heal and all trace of the portal of entry to be lost. 9. Apparently the best means of combating the spread of bovine infection in children, so long as removal of the source is not tackled, is the avoidance of everything likely to cause intestinal catarrh and the use of sterilised milk.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Oct. 15th, the President, Mr. R. G. Hogarth, being in the chair.—Mr. H. J. Gauvain, medical superintendent of the Lord Mayor Treloar Cripples' Hospital, Alton, delivered the inaugural address on Conservative Measures in the Treatment of Surgical Tuberculosis. He confined his remarks to tuberculous disease of bones and joints. The various procedures in the treatment of this disease were rapidly described, and it was shown how the radical school of treatment is being succeeded by a more conservative one, which only recommends partial excision of joints, curetting of sinuses, and aspiration of abscesses, while at the same time persevering with complete rest and immobilisation of the parts affected. He (the speaker) was opposed to surgical interference when avoidable. Great stress was laid on the fact that tuberculous disease is a general disease with local manifestations, and therefore treatment, to be successful, must be general as well as local. As regards the general treatment, these cases were best treated in a special hospital which was situated in a locality climatically especially suitable to the cure of tuberculosis. If a marine spot were selected for the special hospital it should be on the beach with a wide foreshore and facing the prevailing winds. The subsoil should be chalk or sandstone. Of course, suitable hygienic arrangements were essential, and the diet should be good, plain ordinary food. The special diet advocated by Ferrier for the calcification of tuberculous lesions was outlined. Turning to specific drug treatment, Mr. Gauvain was of opinion that, given suitable general and mechanical treatment, the use of tuberculin was limited and should usually not be advocated. Among the adjuvant methods of treatment, Bier's treatment, X rays, and the "sun treatment" as recommended by Rollier were all useful in special cases. Heliotherapeutic measures had been very successfully employed at Alton, and the precautions to be taken and the advantages and limitations were outlined. The necessity for careful local and orthopædic treatment was emphasised and, by means of a series of splendid lantern slides, the audience was shown in detail the mechanical methods employed at Alton. The box-splints, back-door splints, the swinging and wheelbarrow splints were all described in great detail,[1] and it was explained how by these methods the muscular spasm and angular deformities of spinal caries were overcome. An attempt is now being made at Alton to cure the worst cases of angular curvature by means of a complicated system of extension and counter extension, and slides were shown demonstrating the encouraging results already obtained. After the deformity was corrected the parts were immobilised in a plaster casing for the requisite period of time, varying with individual cases. Before applying the plaster jacket on a suspended patient it was desirable to gradually tilt the patient to the vertical position to avoid syncope. A cinematograph film was then thrown on the screen demonstrating the application of a plaster jacket for cervical caries, Mr. Gauvain pointing out the essential details as the film was shown. When the plaster jacket is discarded a plaster positive of the patient's trunk is made and on this a celluloid jacket is manufactured. In order to overcome the inflammable properties of celluloid, celluloid in solution in acetone is denitrated by the addition of a supersaturated solution of calcium chloride. The resulting mixture, when dry, is non-inflammable, but preserves the other essential physical qualities of ordinary celluloid. The solution is painted on to strips of muslin on the cast, and after drying a perfect celluloid casing is obtained which makes an ideal jacket. Turning to abscesses, Mr. Gauvain described the methods of aspirating. The needle should be inserted as far from the abscess as possible and through a wide extent of healthy tissue. Thick caseous material was first liquefied by injecting a solution of thymol 1 part, camphor 2 parts, and ether 3 parts. Where the pus is fluid and the abscess thin-walled a 10 per cent. solution of sterile iodoform in ether is injected into the abscess cavity, and this promotes sclerosis and fibrosis in the walls. The great importance of avoiding sinus formation was emphasised, as sinuses form the most serious complications associated with tuberculous arthritis. Modern methods of treating sinuses were reviewed and their indications explained.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Oct. 2nd. Dr. H. N. Fletcher showed a case of Malignant Disease of the Mamma in a middle-aged man, and an enormously Enlarged Testicle, either a sarcoma or gumma; also a post-mortem specimen of Tuberculous Kidney which had simulated renal colic by occurrence of attacks of intense pain, and absence on repeated examination of tubercle bacilli in urine.—Dr. C. F. Bailey showed a case of Actinomycosis of the Cheek entirely cured by use of X rays after failure of large doses of potassium iodide.—Dr. W. Broadbent showed a Tumour of the Left Crus in a child who had suffered from complete left third nerve paralysis and right hemiplegic spasm; also a specimen of Cerebral Hæmorrhage in a child following embolism (also seen in specimen) during the course of ulcerative endocarditis.—Dr. L. A. Parry read a paper on the Possibility of Premature Interment. He pointed out that there was a very widespread belief among the general public, especially the educated and intelligent public, of the possibility of this dreadful catastrophe, and as proof of this he instanced the large number of well-known people who left directions in their wills for the taking of special precautions against live burial, and the frequency with which applications were made to medical men by relatives of deceased people to verify death by special tests. He discussed the many signs of death, and held that although there was only one absolutely incontrovertible sign—namely, putrefaction—yet a combination of certain of them, even in the absence of putrefaction, made the diagnosis of death absolutely sure. He next discussed the various conditions which might be mistaken for death, and concluded by pointing out that one could assure those who had doubts on the subject that, provided signs of death were very carefully verified, no doubt could remain in a trained observer's mind as to the absolute certainty of the absence of life, but pointed out how seldom in this country careful observation was made.—The paper was discussed by Dr. R. J. Ryle, who emphasised the importance of flaccidity and loss of tension in the eyes; Mr. H. H. Taylor, who referred to the value of the ophthalmoscope owing to sudden loss of circulation in retinal vessels immediately following death; and Dr. H. M. Galt, who pointed out that in this country the great safeguard was length of time ensuing before burial, and he considered that with reasonable care premature interment should be impossible.—Dr. Parry suitably replied.—Dr. Ryle read some notes on the Habitual Inebriate. He said that the "habitual inebriate" as distinguished from the common reckless hard drinker was "one who (in the words of Dr. Branthwaite) may or may not desire to live soberly but cannot do so unless some change takes place in his mental state." The study of Dr. Branthwaite coincided

[1] THE LANCET, March 4th, 1911, p. 568; August 10th, 1912, p. 356.

with that of Dr. F. W. Mott at Claybury Asylum in pointing to habitual inebriety as being rather an evidence of an unsound mind than a cause of it. This, however, was not correctly put in the common words, "Drink is a disease," which obliterated the distinction between the voluntary actions of the inebriate and the involuntary actions of the subjects of epilepsy or intestinal obstructions. As to the innumerable secret or advertised remedies, some cures might be found for all or most of them, but with regard to all of them, as also with regard to hypodermic injections of atropine and strychnine, it was probable that the treatment owed its efficacy to mental and not to pharmaceutical factors. The most important element in the treatment in every case and under all methods was the personal impression made and influence gained by the medical attendant and its use in gradually encouraging and aiding the restoration of the patient's own will. Professor William James—"the only remedy for dipsomania is religiomania"—indicated by an exaggeration the same truth. Treatment in inebriate homes and retreats still left much to be done. For increased power in control and early influence they must await the new and long-promised amended Inebriates Act.—Dr. Broadbent, Mr. G. Morgan, and Mr. Taylor took part in the discussion which followed.

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held at St. John's Hospital, Leicester-square, on Oct. 21st, Dr. Morgan Dockrell, the President, being in the chair.—The following clinical cases were shown:—Dr. J. L. Bunch: 1. A case of Congenital Syphilis in a man, in which a portion of the nose had been destroyed; an artificial nose had been fitted. 2. A man with a Lesion on the Right Arm which showed induration and scarring and a loss of sensation which might suggest the presence of Hansen's bacillus.—Dr. W. Griffith showed a case of Ichthyosis in a boy aged 13, in which vapour baths proved very useful in getting rid of the scales; thyroid extract was given also.—The President showed a case of Ulerythema and Macular Syphilide in a woman, the former condition commencing in June, 1912, and affecting the bridge of the nose and the under portion of both eyes; the chancre and macular rash developed in November, 1912. 2. A case of Epidermolysis Bullosa on the soles of both feet in a boy aged 16, which had existed since birth, the father having bullæ on both feet as well.—Dr. W. Knowsley Sibley showed: 1. A case of Nævus Linearis Bilateralis in a boy aged 16; the condition commenced at the age of three months. A section was taken which on examination was found to compare well with the histology of acanthosis nigricans. 2. A very unusual case of Lupus Erythematosus, the disease encircling both the eyes and a little on the bridge of the nose and ears.—Mr. C. H. Mills showed a case of Seborrhœa-Psoriasis which had developed syphilis.—Dr. Bunch read a paper on Some Methods of Treating Syphilis, in which he discussed the administration of mercury and treatment by salvarsan and neosalvarsan.—The President, Dr. Griffith, and Dr. R. Prosser White joined in the discussion, and Dr. Bunch replied.—Dr. Griffith showed some cases of old Lupus fitted with artificial noses.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in Liverpool on Oct. 17th, Dr. W. E. Fothergill (Manchester), the President, being in the chair.—A selection of Old Illustrated Works on Obstetrics, including three copies of Raynald's "Byrth of Mankynd," were displayed by permission of the honorary librarian of the Liverpool Medical Institute.—Dr. Briggs (Liverpool) showed a collection of Deformed Pelves and a series of plaster-of-Paris casts of Face Presentations.—Dr. Fothergill showed a specimen of Cæsarean Hysterectomy for Fibroid. The fibroid was on the anterior wall of the uterus, low down, and completely prevented the passage of the head. Cæsarean section was performed, thereby saving both mother and child.—Dr. J. E. Gemmell (Liverpool) showed a Fibro-myoma complicating the Puerperium. The child was born without any difficulty, but symptoms of sepsis occurred on the third day, necessitating the removal of the necrosing tumour.—Dr. C. Oldfield (Leeds) read the notes of a case of Bilateral Ovarian Cysts removed during the third month of pregnancy which continued to full term. No signs of other ovarian tissue could be found in the pelvis and none was left from these two ovaries. For pregnancy to continue after removal of both ovaries is contrary to experimental evidence.—Dr. A. Donald (Manchester) read the notes of a case of Puerperal Pyæmia which continued five months in spite of lantol and vaccines. At one time the patient developed all the signs of pelvic thrombosis, but none could be discovered on operation.—Dr. W. Fletcher Shaw (Manchester) showed a specimen of Perithelioma of the Uterus which occurred as a polypus, the size of a hen's egg, protruding from the external os. Two years previously he had removed a simple fibroid polypus from the same uterus.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Oct. 24th, Dr. David Ross, the President, being in the chair.—Mr. P. Maynard Heath showed: 1. A woman, aged 44, who had a tumour on the left lower alveolus ulcerating, probably due to the pressure of the upper teeth on it, diagnosed as a fibrous epulis. There was no enlargement of glands. 2. A man, aged 60, with epithelioma of the soft palate and both anterior faucial pillars which had been present for a year. There was ulceration on the growth. Glands at the angles of the jaw were enlarged. 3. A woman with a tumour about 5 cm. transversely on the clavicle, which bone was seen by a skiagram to be fractured within the swelling. There had been a "lump" on a rib a year ago. Wassermann's reaction was positive. Neosalvarsan had been injected. 4. A boy, aged 14, with Bazin's disease present for two months. 5. A boy, aged 4 years, with birth palsy of right arm. 6. A man, aged 62, with growth on left side of mid-tongue with only a five weeks' history and without enlarged glands.—Dr. P. Hamill showed skiagrams of the hands and skull of a man, aged 40, the subject of acromegaly; the pituitary fossa was enlarged. 2. A photograph of a cystic adenoma of the mid-cerebral base with pressure on the optic chiasma. 3. A skiagram of a man, aged 50, showing a pyloric growth which proved to be malignant after removal by Mr. Maynard Heath. 4. A skiagram of a woman, aged 23, the subject of pyloric carcinoma, also removed by Mr. Maynard Heath.

HARVEIAN SOCIETY.—A clinical meeting of this society was held at Paddington Green Children's Hospital on Oct. 16th, Dr. Leonard G. Guthrie, the President, being in the chair. The following cases were shown:— The President: Several cases of Congenital Hereditary Nystagmus and Head Rolling.—Dr. G. A. Sutherland: 1. A case of Cœliac Disease in a child. 2. A child with Auricular Fibrillation, of which some interesting heart tracings were exhibited. 3. A child three years after the Removal of the Left Kidney for Sarcoma by Mr. F. F. Burghard; for two years there was an apparent cure, now recurrence had taken place.—Mr. E. G. Gauntlett: 1. A case of Ulnar Paralysis following the separation of the lower epiphysis of the humerus; the nerve had been freed from the callus by which it was surrounded. 2. A case of Ischæmic Paralysis after a fracture of the olecranon.—Dr. S. H. Hay: A case of Bacilluria.—Mr. Haldin D. Davis: An extremely severe case of Ichthyosis in a young man.—Mr. Leonard C. W. Balls: A series of dental cases, ranging from 6 to 10 years.—Mr. Duncan C. L. Fitzwilliams: 1. A case in which a Lipoma had been removed from under the parietal pleura, also a Fibro-lipoma from under the deltoid; it had been attached to the capsule of the shoulder-joint. 2. A case of Tumour in the upper part of the abdomen in a child, the nature of which was uncertain.—Dr. H. W. Perkins had arranged an exhibition of interesting microscopic and pathological specimens.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, W.C., on Oct. 17th, Dr. F. J. Allan being in the chair. The claim account showed a slight margin against the society, and it would appear that the claims will be heavy for the whole year. New proposals were up to the average, and the proposals for additional benefits showed a steady increase. This being the sixth quinquennial valuation year the results are awaited with interest. In spite of the serious depreciation of gilt-edged securities, in which a large part of the society's funds are invested, and the consequent writing-down of these, it is expected that a substantial surplus will be shown this year as in the previous reports. The committee wish it to be known that dental surgeons are eligible for membership. Full information may be obtained from the secretary, Mr. B. Sutton, 33, Chancery-lane, London, W.C.

Reviews and Notices of Books.

The Elements of Bacteriological Technique: A Laboratory Guide for Medical, Dental, and Technical Students. By J. W. H. EYRE, M.D., M.S. Durh., F.R.S. Edin., Director of the Bacteriological Department of Guy's Hospital and Lecturer on Bacteriology in the Medical and Dental Schools; sometime Hunterian Professor, Royal College of Surgeons, England. Second edition, rewritten and enlarged. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 518. Price 13*s.* net.

AT the time of the appearance of the first edition of Dr. Eyre's work it was much the most important, if not actually the only English, book which dealt with bacteriological technique. This is still to a great extent true of the second edition, though recently an English translation of Dr. Besson's work, which covers much the same ground but is much more expensive, has appeared. In our review of the first edition we pointed out that in a work such as this choice had to be made between complete, and consequently lengthy, descriptions of technique, such as would suffice without practical demonstrations of the methods, and the shorter description which implied the necessary assistance of a demonstrator. Dr. Eyre recognises the importance of practical instruction in the laboratory, but chooses the first alternative, and gives such clear and detailed descriptions of methods as to reduce the need for a demonstrator to a minimum, at any rate for those who have had some laboratory training.

During the ten years which have elapsed since the first edition appeared numerous changes in technique and a very large number of new methods have been introduced. In bacteriology it is certainly the case that all that is new is not necessarily true, and that the old methods have stood the test of time better than some recent introductions, so that it has only been necessary to increase the present edition by some 140 pages. The culture media have been divided into ordinary and special media. This has involved some rearrangement, and a chapter has been devoted to those special and very numerous media (the formulæ alone requiring some 30 pages) devised by various workers to meet individual needs. Additions have also been called for to deal with the changed relations between bacteriology and clinical medicine, such as descriptions of opsonic technique, the methods of dark-ground illumination and use of the ultramicroscope, Burri's Indian-ink method, and methods for the demonstration of organisms, especially spirochætæ, which were unknown at the time of the first edition.

There are important additions also in the chapter on methods of identification and study of micro-organisms, where immunisation methods and those for the preparation and standardisation of hæmolytic sera, and the storage of hæmolysin, now find a place. The chapter on the experimental inoculation of animals has been lengthened, and some description of the natural diseases of the animals usually employed is given. A new chapter on the study of experimental infections during life includes a useful section on the comparative hæmocytology of laboratory animals and a description of the serological examination of the blood for the demonstration and estimation of agglutinin, opsonin, and bacteriolysin. The outlines for the study of pathogenic bacteria have wisely been reduced, as this section was a little out of line with the rest of the book. There have been both rearrangement and the introduction of much new matter into the chapter on bacteriological analyses. The examination of oysters and other shell-fish is dealt with; antiseptics and their consideration no longer occur in two places; and the rather thorny question of the standardisation of disinfectants is brought up to date. Water analysis is treated with a clear recognition that the results are wanted for a definite practical purpose and not to constitute a complete study of the water flora. Some useful tables are given in an appendix.

The book is extremely well produced and will certainly find a place in every bacteriological laboratory.

Treatment of Tuberculosis. By ALBERT ROBIN, Professor of Clinical Therapeutics at the Paris Faculty of Medicine. Translated by Dr. LÉON BLANC, Physician at Aix-les-Bains; with the assistance of H. DE MÉRIC, Surgeon to the French Hospital, London. London: J. and A. Churchill. 1913. Pp. 616. Price 18*s.*

Dr. Robin's views on tuberculosis are well known in France, but in this country they have not hitherto had the publicity which they merit; for although some of his contentions have not met with general acceptance, nevertheless the practical conclusions at which he has arrived with regard to the therapeutics of the disease, especially of the pulmonary variety, are well worth careful attention.

The first part of the work is devoted to a consideration of "the soil of pulmonary tuberculosis and important indications as to treatment." Dr. Robin lays stress on the importance of observing the respiratory exchanges in all individuals suspected of harbouring tuberculous disease, for he maintains that "phthisical" patients consume more oxygen and produce more carbonic acid per kilogramme of weight and per minute in time than healthy subjects. This augmentation, he says, is entirely due to an increase of the pulmonary ventilation From other considerations he is firmly convinced that the acceleration of the respiratory exchanges is a manifestation of a soil prone to, or already the seat of, tubercle. He further contends that there are therapeutic agents qualified to diminish exaggerated gaseous exchanges, that it is possible to recognise their power by experience and to fix their doses and the best methods of employing them in the necessarily precise manner. Amongst the pharmaceutical agents which limit the respiratory exchanges he mentions cod-liver oil, tannic acid, arsenical and antimonial preparations (these last in very small doses), and inhalations of air containing an excess of nitrogen. These deductions have not been looked upon with favour by most observers, and English physicians are practically silent on the subject.

The same remark applies to Dr. Robin's observations on "organic demineralisation" and the "principles of remineralisation." He states that if a comparison be drawn up between a large number of phthisical patients at different periods of the malady and also the average of the results be taken by periods, it will be found that their urinary coefficient of demineralisation—that is to say, the existing relation between the inorganic residue of the urine and the total residue (normal state, 30 to 32 per cent.)—is raised at the period of predisposition, is again increased during the first perceptible signs of infection, is afterwards a little lowered at the second period, and clearly falls at the third period. From the principle of "remineralisation" which is indicated in predisposed individuals and in the early stages of the disease he proposes a definite line of treatment—namely, the administration of preparations which will introduce into the system the substances necessary to make up the loss which has been sustained. Of these the chief is fresh bone powder, together with precipitated carbonate of calcium, carbonate of magnesium, and a little lactose or sugar.

Dr. Robin's remarks on direct and indirect antiseptic medication are more in accord with generally accepted ideas. In discussing the use of tuberculin he adopts a moderate tone. He says that it is not wise to rely on a single method of technique, but an endeavour should be made to obtain with regard to each individual case the dose of tuberculin

capable of producing local reaction, which must, however, be moderate, and all thermic and general reactions should be avoided as far as possible.

Sanatorium treatment is discussed in the portion of the book devoted to hygiene and alimentation. He admits that although the sanatorium has not succeeded in becoming a recognised institution in France in the official anti-tuberculous armamentarium, yet it constitutes the most certain medium by the help of which tuberculous patients have "at least a chance of cure." He rightly points out, however, that when a patient has the means and the will to undergo treatment, he can create, under his doctor's direction, a sanatorium in his own home. Some valuable hints and suggestions are made as to the general management of a patient suffering from pulmonary tuberculosis, and the last part of the work, which is under the heading "Social Defence against Tuberculosis," contains excellent advice and comments upon the duties of the individual and of the community in regard to tuberculous disease.

Dr. Robin's remarks are throughout for the most part of an essentially practical character, and therefore for clinical purposes the book will be found of value to those engaged in the general practice of their profession. The translators have performed their task admirably, and have produced an excellent English edition of the French work.

Clinical Pathology. By P. N. PANTON, M.A., M.B., B.C. Cantab., Clinical Pathologist to the London Hospital; formerly Assistant Director of the Jenner Clinical Laboratory, St. Thomas's Hospital. With 13 plates (coloured) and 45 figures. London: J. and A. Churchill. 1913. Pp. 446. Price 12*s.* 6*d.* net.

THE appearance of a number of new books dealing either with the methods of laboratory investigation or with the application of the results obtained in the laboratory to practical medicine suggests that there is an increasing demand for concise information on these matters. Be that as it may, Dr. Panton assumes that the senior student and the practitioner have no overpowering desire for multiplicity of tests, and he has, therefore, undertaken to select for them one or, at most, two reliable methods for conducting each particular investigation, to describe such methods clearly and exactly, to explain the meaning of the abnormalities encountered, and in some measure to correlate the laboratory findings with the clinical symptoms. Of this task he has acquitted himself well, and his efforts have been admirably supported by both artist and publisher, since the subject matter is set out in a very attractive fashion.

In all there are seven sections, dealing in turn with the blood, pathogenic bacteria, puncture fluids, urine, the normal and abnormal characters of the alimentary system, the eye, the skin and the respiratory tract, and concluding with a section on the histology of inflammatory lesions and new growths. The section on blood is particularly clearly arranged and the colour drawings of Leishman-stained cells, illustrating the cytology of blood and of puncture fluids, are excellent. These chapters will, no doubt, be much appreciated by many, although it is safe to say that some will cavil at the suggested origin of certain of the leucocytes. A readable account is given of bacteriological technique as applied to everyday ward work; and the descriptions of the various pathogenic micro-organisms, although extremely sketchy from the expert bacteriologist's point of view, are sufficient for the needs of the clinician. An interesting feature consists in a note of the bacteriological flora, parasitic and saprophytic, normally present, which precedes the description of that met with in disease conditions in such situations as the mouth, the eye, &c. Some omissions may be noted; thus, there is no mention of luetin or of Friedländer's pneumobacillus, nor can we find any method for the estimation of urea in the blood, but these will no doubt be remedied in a future edition.

On the whole, "Clinical Pathology" makes a very pleasing impression upon us. In its general arrangement Dr. Panton has displayed considerable artistic skill, and the free use of clarendon type not only emphasises important points, but also renders subsequent reference an easy matter; while upon the selection of methods from the many sources at his disposal he has expended much care and exercised a wise discretion.

Stuttering and Lisping. By E. W. SCRIPTURE, Ph.D. Leipzig, M.D. Munich, Associate in Psychiatry, Columbia University, &c. New York: The Macmillan Company. Pp. 251. Price 6*s.* 6*d.* net.

Dr. Scripture has had exceptional experience, both clinically and experimentally, in the study of phonetics, and he has collected the results of his experience in a book prepared to meet the needs of physicians and teachers, and calculated to solve the problem of what to do with a lisping or a stuttering child. Dr. Scripture states that in several European countries the State has established special opportunities for treating children with speech defects. In several of the foremost medical schools speech clinics have been established. The author himself, in the Vanderbilt clinic, controls a speech department where thousands of cases have been treated. It is clear that with this development of a science of normal and pathological speech the treatment of these defects stands upon an entirely new basis.

We have formed the opinion that the methods so fully particularised in this book are both scientific and practical, and we recommend it to the notice of those who are concerned with the subject. Some 40 pages are devoted to exercises along the lines carefully explained, with diagrams and otherwise, in the earlier part of the book. Nor does the author ignore the psychical element in many of his cases, and he resorts, where he deems it advisable, to the technique of psycho-analysis to further his ends.

Eléments d'Anatomie et de Physiologie Médicales. Publiés sous la direction de L. LANDOUZY et LÉON BERNARD par MM. LÉON BERNARD, GOUGEROT, HALBRON, S. I. DE JONG, LAEDERICH, LORTAT-JACOB, SALOMON, SÉZARY, VITRY. Paris: Masson et Cie. Pp. 770, avec 336 figures en noir et en couleurs et 6 planches hors texte en couleurs. Price 20 francs.

THIS book, published under the direction of the genial Professor "de la Clinique Laennec" and dean of the Medical Faculty of the University of Paris, M. L. Landouzy, and M. L. Bernard, *agrégé* of the Faculty of Medicine, also of the same hospital and university, is, according to Professor Landouzy, the partial realisation of a book long ago thought of—a book that should present anatomy and physiology adapted and applied to internal medicine. Anatomy alone does not suffice—"the cry of diseased organs" must be assuaged through a knowledge of physiology. In fact, the text represents the instruction given at conferences by certain of the physicians at the Clinique Médicale Laennec. The advice of Landouzy—and his authority is high—is "to think anatomically and physiologically."

Perhaps we can best show the variety and thoroughness of the work by giving an account of the subjects dealt with and the names of the authors. At once the reader is introduced in Chapter I. to the stomach. As in most French books, systematic and orderly arrangement pervades the text, so whether it be stomach, or hypophysis, skin or kidney, the same general arrangement is adopted. Anatomy, macroscopic and microscopic; physiology, normal and pathological; clinical applications and syndromes, when

they arise; and even "insufficiency"—a favourite word in French medical literature—are set forth in this order. M. Vitry is responsible for the chapters on the stomach, intestines, pancreas, and genital apparatus; M. Laederich for the liver, kidneys, and alimentary metabolism; M. S. I. de Jong for the upper respiratory passages, thorax, lungs, and serous membranes; M. Halbron for heart, blood-vessels, and lymphatics; M. Salomon for blood and skin; M. Gougerot for lymphatic tissue and lymphatic ganglia, myeloid and osseous tissue, spleen, thymus, unity of the lymphopoietic and hæmatopoietic tissues, and mesodermic tissues; M. Léon Bernard for suprarenal glands, thyroparathyroid apparatus, hypophysis; M. Sézary for nervous system, brain, "tronc cérébral" and cerebellum, and centripetal conducting paths; and M. L. Lortat-Jacob for spinal cord, meninges, sympathetic system, and cranial and spinal nerves.

The text is admirably printed; the illustrations in the text, some of them from well-known French text-books and others original, are reproduced with a clearness and effectiveness that leave nothing to be desired. The colour plates also are effective. But it is hard to believe, in the light of modern physiology, that the reconstruction of the "albuminoid" molecule takes place in the wall of the intestine or in the liver (p. 128). Plate III. is a large, highly coloured, suggestive, and imaginative "tableau" on alimentary metabolism. It is quite well worthy of study. The well-known work of Poirier-Charpy is liberally drawn on for illustrations.

We think the chapter on the heart leaves something to be desired, more especially in relation to its nerves and the recent researches of Flack and others. The scheme of the ganglia of the heart might have been replaced by something "human." The pathological physiology of the author, it seems to us, is better than his normal physiology. The chapters on the blood and lymphatic system are excellent, and so are those on bone marrow, the spleen, and other ductless glands. The parathyroids in man and animals are well illustrated, as is the pituitary body, though in the last case the names of French observers preponderate. The remainder of the work is chiefly taken up with the nervous system.

This is an excellent, suggestive, and practical work which will prove most useful to the practitioner when he wishes to recall the facts of physiology, anatomy, and pathology in their application to, and in the explanation of, the phenomena observed at the bedside. We think Professor Laudouzy and his collaborators have in no small degree realised their aim—an aim at once scientific and practical.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. Nos. 54, 55, 57, 58, and 59. Calcutta: Superintendent of Government Printing, India. 1912, 1913.

OF these memoirs No. 57 deals with the Flagellate Protozoa of the genera Herpetomonas, Crithidia, and Rhynchoidomonas, written by Captain W. S. Patton, I.M.S. The remaining parts of the series are from the researches of Captain F. W. Cragg, I.M.S., and are concerned with the mouth structures and the general anatomy of various blood-sucking flies. The mouth parts of these insects are carefully studied by series of sections, the only method of satisfactorily making out the exact relations of the various appendages which together constitute the biting and suctorial apparatus of these creatures. Dissections are not of themselves sufficient in the case of such small insects to explain the various mechanisms involved. Large, and therefore readily intelligible, drawings explain the mutual positions of the various parts, and to some extent illustrate the histology. The minute structure, however, is less important from the point of view of the author than the morphology of the several appendages. A more comprehensive memoir, the Structure of Hæmatopota Pluvialis (Meigen), also by Captain Cragg, contains a full account of the anatomy of this Tabanid fly. In view of the propagation of parasites it is clearly important to ascertain not only the life-history but the bodily structure of the flies which carry certain stages of the parasites transmitted by them to man and various mammals. This particular species is well known in this country under the name of "clegg," or "horse-fly," and it is only the female which bites, the male being a flower feeder. Moreover, the male is but rarely met with, owing possibly to a lack of knowledge of its habits and range. The author, however, has a more ingenious explanation of the apparent rarity of males. He thinks that the structure of the copulatory apparatus brings it about that the viscera are fatally disarranged by the action of the male intromittent organ. This organ is held by the bursa of the female in such a way that it seems unlikely that it can be drawn out unharmed after fertilisation.

Acute Poliomyelitis (Heine-Medin's Disease). By Dr. IVAN WICKMAN, of Stockholm. Authorised English translation by Dr. W. J. A. MALONEY, F.R.S.E. Illustrated. New York: The Journal of Nervous and Mental Disease Publishing Company. 1913. Pp. 135. Price $3.00.

THOSE who are unfamiliar with the German language will welcome this translation of Wickman's studies on acute poliomyelitis. The exceptional opportunities which the Swedish author has had, and the conspicuous ability with which he has handled both clinical and pathological material, render his work authoritative; to all students of the disease it is indispensable. In this volume will be found careful description and differentiation of the common and uncommon clinical types, and an account of the pathological anatomy which leaves nothing to be desired. The pathogenesis and experimental pathology of the disease are fully discussed, while the chapter on epidemiology contains many interesting and significant facts. There is a good bibliography. Dr. Wickman's work is a classic in the study of the disease known as acute poliomyelitis, and we welcome it in its English garb to a wider circle of readers.

The Course of Operative Surgery: A Handbook for Practitioners and Students. By Professor Dr. VICTOR SCHMIEDEN, *privat-docent* of Surgery in the University of Berlin, Assistant in the Royal Surgical University Clinic. Second enlarged edition, with a foreword by Professor Dr. A. BIER. Translated and edited by ARTHUR TURNBULL, M.B., M.A., B.Sc. Glasg., Demonstrator of Anatomy in the University of Glasgow. London: Baillière, Tindall, and Cox. Pp. 345. Price 12*s.* 6*d.* net.

THE teaching of operative surgery has undergone many and great alterations during the last 20 years. Formerly little was taught on the cadaver beyond the ligature of vessels, amputations, and such operations as trephining. The increasing importance of abdominal surgery has led to the devotion of more time during a course of operative surgery to operations on the abdomen.

The work before us is one of the most satisfactory we know, for the descriptions of the operations are clear and exact, and the explanations of the reasons for the various stages are given. The illustrations are numerous and adequate, and we can express our approval of the work, though we can hardly go as far as the translator when he confidently expresses his opinion that "the book will become the student's handbook in every college where English is the medium of surgical instruction." The translator has, on the whole, done his work well, but in the names of the instruments he has not always given the usual English equivalent; for instance, we find an

ordinary scalpel described as a "surgical knife," and what in this country are described as "artery forceps" or "Spencer Wells forceps" are here described as "Péan's forceps," which is, indeed, the name given to them on the continent of Europe, though it is practically unknown in the British Isles. The ordinary "rat-tooth" or "mouth-tooth" forceps are called here "surgical forceps," a name which is too indefinite. "Lion forceps" are described as "bone forceps," again an indefinite name. The trephine shown is of a pattern which is hardly ever used now in this country.

It may be said that all the points to which we have taken exception are small, and we agree; our main object in mentioning them here is so that they may be remedied when this work comes to a second edition in its English dress The book should have a wide circulation, for it deserves it.

Disturbances of the Visual Functions. By Professor W. LOHMANN, Chief Physician to the University Eye Clinic, Munich. Translated by ANGUS MACNAB, M.B. Edin., F.R.C.S. Eng., Ophthalmic Surgeon to King Edward VII. Hospital, Windsor. With 39 illustrations in the text, some in colours. London: John Bale, Sons, and Danielsson, Limited. 1913. Pp. 185. Price 15*s.* net.

WE have already reviewed the German edition of this book in THE LANCET of Feb. 22nd, 1913, so that it is unnecessary to repeat any more of our opinions about the subject matter beyond the general statement that we found it very trustworthy. Mr. Macnab has done good service in translating the book, and the translation is also very good. He has made no attempt to annotate the work in any way. We hope that Professor Lohmann's book will find many English readers.

Die biologischen Grundlagen der sekundären Geschlechtscharaktere. Von Dr. JULIUS TANDLER und Dr. SIEGFRIED GROSZ. With 23 figures in the text. Berlin: Julius Springer. 1913. Pp. 169. Price 8 marks; bound, 8.80 marks.

IN this book the authors discuss and bring forward evidence in favour of the view which they hold with regard to secondary sex characteristics. In their opinion secondary sex characteristics are properties peculiar to a species or order of vertebrates, and have no primary relationship to the organs of generation. Thus, for instance, they hold that the mamma, the outcome of an agglomeration of sweat glands, has only later become an organ of different function and included within the sphere of the reproductive system. The beard of man and of the apes is considered to be equally characteristic of species, and, as they point out, the upper lip of the fœtus is covered with a hirsute growth which attains an equal development in both sexes. So, too, they maintain that the antlers of deer are a special characteristic of unknown function which only later acquire a relationship to the sex organs. In the fœtus of the roe deer there is a trace of an antler with the same appearance in both sexes, but in the male it progresses, while in the female it regresses. Then in the reindeer antlers are met with in both sexes, and those of the female are not affected by castration.

In this monograph the authors consider the effect of castration both upon animals and man, including a description of the results of experimental castration and parasitic castration. The question of the exact nature of eunuchs and of those strange cases of premature sexual development which from time to time occur and their relation to the ductless glands is discussed. In this connexion there is also a short account of the subject of hermaphroditism, but the most interesting section in the book is that dealing with the problem of those curious cells, the so-called interstitial cells of the testis and ovary. their development, their function, and the effect upon them of the Roentgen rays. A very interesting account is given of the changes found in the genital glands in cases of cryptorchismus and of the questions associated with this defect.

The book contains a good deal of information, and will be of value to those interested in this fascinating subject.

Veröffentlichungen aus dem Gebiete des Militär-Sanitätswesens. Herausgegeben von der Medizinal-Abteilung des Königlich Preussischen Kriegsministeriums. Heft 53. *Die Schussverletzungen des Schädels im Kriege, Beobachtungen und Erfahrungen während des Russisch-Japanischen Krieges, 1904-1905.* Von OTTO HOLBECK, s.Z. älterer Arzt der Eigenen Fliegenden Kolonne Ihrer Majestät der Kaiserin Maria Feodorowna. Illustrated. Berlin: August Hirschwald. Pp. 479. Price 12 marks.

THE introduction within recent years of the high-speed small-bore bullet revolutionised in great part the teaching on the subject of bullet wounds. Especially was this true of bullet injuries of bones, and above all of injuries of the skull from bullets. This volume, which forms one section of a series of official publications on matters relating to military medicine and surgery, contains a careful study of the effects of bullets and other projectiles on the skull and its contents, the form of the wounds produced, the symptoms to which they give rise, and the affections of the special senses. Nearly a hundred pages are devoted to the question of treatment, and notes are given of 435 cases which have been chosen to illustrate the various points in connexion with the different injuries to the skull and its contents, and in many cases the temperature and pulse chart is added. An extensive bibliography contains the most important recent contributions to the subject, and this list of papers and works is classified according to the wars in which the writers have served, and also according to the part of the subject dealt with.

The work as a whole is very thorough and trustworthy, and it forms a notable contribution to an important subject.

MISCELLANEOUS VOLUMES.

AGAIN we have a miscellaneous assortment of volumes and pamphlets to comment on.

In *Beauty for Ashes* (London: L. Upcott Gill and Son, Limited. Pp. 113. Price 1*s.* net) Lady HENRY SOMERSET gives a moving picture of the work done for the redemption of women inebriates at the Industrial Farm Colony, Duxhurst, near Reigate. There is nothing dry about the book; on the contrary, it forms interesting reading throughout, and the conception of the various forms and predisposing causes of inebriety in women is sound. The colony was started 20 years ago. The Manor House of Duxhurst forms a home, retired yet not isolated, for patients of more ample means. The meadows which separate it from the road are now occupied by cottages forming a village colony, grouped around a pretty village green, where women of all classes, but of less ample means, live under the care of a sister in charge of each cottage. Each new patient goes first into the hospital, and there remains long enough for the case to be understood and classified, and for the moods of depression and restlessness that are apt to beset her and give rise to the craving, to be studied and met as far as possible By the time she leaves the hospital she will have lost much of her shyness and be ready to take her place in the social life of the village. She is then placed in a cottage among the group most likely to be congenial to her, the sister in charge of each cottage generally having some particular temperamental bent: one is more suited to the young, another to the more mature, a third may be of a Bohemian type, while the sympathies of a fourth may trend

rather towards the conventional. Work of various kinds, particularly gardening, basket-making, plain and artistic sewing, weaving, and the like, is provided, and fresh air and sunlight are pressed into service by an out-of-door life. The village also offers a little social world to ladies at the Manor House, which they can enter without encountering the vulgar curiosity they would be likely to arouse in other retreats, for there they find women of all classes coming and going, occupied with their work, and too much accustomed to seeing new patients to regard their arrival with anything but a polite indifference. Thus, doors have been opened into many a rich woman's heart for fellow feeling and sympathy with those of other classes. Another remarkable institution is the cottage for the children of drunkards, where some 30 boys and girls are cared for. Their presence adds a joyous note to the village life, emphasises the fact that not everyone there has been a misdoer, and thus speaks to the women's hearts in a way nothing else could do. The illustrations in the book show the singular beauty of the surroundings, which is well sustained by the picturesque architecture of the cottages and other buildings. There is a church in the centre of the village, for a religious spirit pervades the institution, though, as may be clearly gathered from one of the stories told (p. 52), no narrowness of view prevails. As to the results obtained, out of 276 patients to be accounted for between 1905 and 1912, 205, all of whom stayed at least one year, are now doing well; 51 failed, 12 were lost sight of, and 7 are still uncertain. This certainly seems a satisfactory record. The homes are carried on entirely by subscription, with the exception of the small sum—from 7*s.* 6*d.* a week upwards, according to her means—paid by the patient or her friends. There is no endowment. Lady Henry Somerset's book should certainly attract increasing attention to the work.——A very useful little handbook for all who are especially interested in deaf persons is *The Deaf*, published for the National Bureau for Promoting the General Welfare of the Deaf by P. S. King and Son (1913. Pp. 75. Price 6*d.* net). It consists of a full list of the national and local agencies for the educational, industrial, and spiritual betterment of the deaf in this country. It contains, in addition, a summary of Acts or portions of Acts of Parliament dealing with the deaf and statistics bearing on the deaf in relation to the census, education, employment, and so forth.——A pamphlet of a similar philanthropic character, but dealing with the care of the young, is *Infant Welfare Centres*, by J. G. GIBBON, D.Sc., published by the National League for Physical Education and Improvement (1913. Pp. 52. Price 6*d.* net, post free for 7*d.*). The pamphlet tells of the work of infant consultations, schools for mothers, and similar institutions, and an appendix contains information concerning such work in Germany, Belgium, and the Netherlands.——Mr. G. L. PEPLER'S pamphlet, *What Town Planning Means* (London: The Garden Cities and Town Planning Association. 1913. Pp. 12. Price 2*d.*, by post 3*d.*), is a concise summary of the powers and obligations of local authorities and landowners. The author describes what a council can do and what an owner can do respectively to further proper town planning; and as regards the cost he points out that it will be much less than what is now being paid for lack of those powers in the past. The latest information on the progress of town planning is included.

Even doctors, we suppose, must have domestic servants, so that in view of the special legislation of recent years that has encompassed the people of these islands in all relations of life it is well that medical practitioners should have at hand a little book to advise them of their rights, duties, obligations, and liabilities in regard to their servants. Such a book is *The Law of Domestic Servants*, by J. D. CASSWELL, B.A., of the Middle Temple (London: Jordan and Sons. 1913. Pp. 126. Price 1*s.* 6*d.* net). The book contains chapters on the nature of domestic service, details relating to the contract of service and its termination, wages, characters and references, the employer's liability to his servant, the master's liability to others for the acts of his servant, various miscellaneous subjects, such as the rights and liabilities of masters and servants to third parties, criminal offences by servants, legacies, and so forth. Finally, there is a chapter on the old age pension, with mode of applying for it, and 26 pages are devoted to the National Insurance Act so far as it affects domestic service, either regular or casual. There is a table of cases cited and a quite useful index.

A serviceable little book for those who travel much in the British Isles is the *Handy Hotel Guide 1913–1914* (London: The Hotel and General Advertising Company, Limited. Pp. 230. Price 2*d.*). It gives a list of selected hotels "free from bias," with the, perhaps necessary, assurance that "we have never received any bribe or pecuniary consideration from any hotel so recommended," arranged under places in alphabetical order, with accommodation, prices, population of town at last census, &c. Particulars are added as to golfing and annual fixtures and events, and information of service to motorists. In the case of some towns details of historical or other general interest are appended. Maps of certain districts are also given.

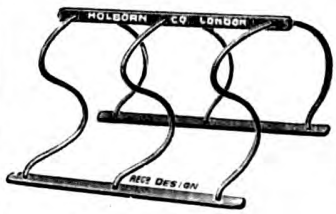
In *Latin Self-Taught* (London: E. Marlborough and Co. 1913. Pp. 144. Price 1*s.*; or cloth, 1*s.* 6*d.*), Mr. JOHN TOPHAM, barrister-at-law, endeavours to resuscitate Latin, making it "live again and serve the purpose of a practical medium for the exchange of ideas, by the simple means of treating it as a living tongue and using it conversationally"—not, of course, a novel method, but one that has unfortunately passed into desuetude for the most part. Obviously it became essential to discard the English or Erasmian pronunciation and revert to that which, with slight variations, is extant in continental countries and universal in the United States. To that end the phonetic system adopted seems fairly efficient. The vocabularies appear to be well assorted, the grammar is concise and sufficient, and the phrases, ordinary and professional, including medical, will be found useful. At the bottom of p. 127 the Latin equivalents for "two tablespoonfuls to be taken" and "the gargle to be used" are transposed. A similar transposition occurs in lines 7, 8, and 9, p. 130. Tables of Latin mottoes, proverbs, and abbreviations complete the book.

JOURNALS AND MAGAZINES.

Zeitschrift für Angewandte Anatomie und Konstitutionslehre. Edited by Dr. J. TANDLER (Vienna), with the assistance of Dr. A. VON EISELSBERG (Vienna), Dr. A. KOLISKO (Vienna), and Dr. F. MARTIUS (Rostock). Vol. I., No. 1. Berlin: Julius Springer. 1913.—This is the first number of a new medical periodical which is intended to deal with subjects coming under the headings of applied anatomy and of the study of the "constitution," as distinguished from individual organs of the body. One of the objects of those who are responsible for the appearance of this publication is to bring anatomy into a closer relationship with clinical work, and to record those advances which are made in anatomical knowledge that have a direct interest to the clinician. Owing to the progress which has been made in pathology, bacteriology, and kindred sciences, there has been a tendency on the part of those especially interested in these subjects largely to dissociate themselves from clinical work, and, on the other hand, physicians and surgeons, being unable to keep thoroughly abreast with the latest researches in purely scientific medicine, have devoted themselves almost entirely

to clinical work. But as a knowledge of anatomy, both of the normal and of the diseased individual, is the basis of medical science, a separation of the two can be only a retrograde step. In this *Zeitschrift*, therefore, articles will appear which will bring out the application of anatomy to clinical work. A further intention on the part of the editors is to lay stress not so much upon a study of the different organs of the body as upon an investigation of the constitutional characters of the human body. Amongst the contributions to this number are: Constitution and Race Hygiene, by Dr. J. Tandler; the Constitutional Factor in the Pathogenesis of Basedow's Disease, by Dr. F. Chvostek; and the Significance of Lymphatism and other Constitutional Factors in the Formation of Gall-stones, by Dr. H. Zellweger. The objects for which this publication has been issued are interesting and deserve support.

Jahreskurse für Aerztliche Fortbildung. August and September, 1913. Munich: Lehmann. Price 18 marks per annum.—A great variety of recent advances in many branches of the healing art are dealt with in the August number. Professor Heubner writes on a few of the fundamental conceptions of drug therapeutics, showing how drugs may act by variations in their solubilities, as in Meyer's theory of the narcotics which are fat-soluble, and by their specific affinities for particular chemical molecules in the tissues. A number of new drugs, such as neosalvasan (which he considers less likely than salvarsan to induce nephritis), atophan, bromine compounds, and colloidal metals, are referred to. Professor Glax gives some account of the therapeutic uses of sea-water, both internally and externally, and Professor Strasser writes on hydrotherapy. Of more general interest is an article on the dietetic treatment of severe cases of diabetes by Professor Strauss, who discusses the relative indications for semi-starvation, eggs and green vegetables, vegetable proteins, and fairly generous carbohydrate feeding, the last, of course, being reserved for cases with threatening acidosis, and best applied in the form of the oatmeal cure. Various "cures" may be taken for a day at a time; thus there are oatmeal porridge days, "drink days," milk days, green vegetables and eggs days, &c. Other articles include a discussion of the effects in susceptible persons of a fall of barometric pressure, such as the cerebral, rheumatic, and catarrhal symptoms from which some suffer when in the centre of a cyclonic depression; some remarks on high frequency current treatment; a rapid review of the many-sided applications of X rays; and an account of the various radio-active metals, such as radium, thorium, uranium, and actinium.



The September issue is largely devoted to a discussion of the problems of State sickness insurance arrangements, and has, therefore, a special interest just at the present time. The conditions prevailing in several large towns are briefly described. Another article deals with the relationship to the State insurance system of workmen's compensation for accidents. This is rather beclouded for the English reader by the enormous number of references to German officials and official systems. The section on forensic medicine is written by Professor Puppe and Dr. Nippe, and includes an article on the signs of death, with special reference to "pseudo-vital reactions," such as post-mortem staining simulating hæmatoma. It is pointed out that fat-embolism, especially in stout women, may be found in the lungs and kidneys after injuries too slight to be of medico-legal significance. Dropsy may be simulated by post-mortem subsidence. Post-mortem burns may show blebs, at least in an œdematous skin, and even a hyperæmic zone. Some help may be obtained in deciding whether bones are human or animal by the precipitin method, and also the arrangement of the Haversian canals is said to be characteristic in man. The post-mortem appearances after death from drinking are discussed, and the development of nodules of calcium and magnesium soaps in the adipose and other tissues of bodies long after death. Professor Sudhoff gives a review of various schools of thought in the history of medicine.

New Inventions.

(1) A COMFORTABLE LEG-CRADLE; AND (2) LIGATURE SPOOL-ATTACHMENT.

As the result of practical experience I have designed a leg-cradle, modified from the ordinary pattern, as shown in Fig. 1. The hoops are, on one side, made concave in the lower part of their ordinary convexity, this hollowing-out allowing the uninjured leg to lie comfortably parallel alongside its fellow, and not in a splayed-out condition, as is the case with ordinary patterns.

FIG. 1.

The suture and ligature spool is designed for rapid and easy suturing and ligaturing. The apparatus (Fig. 2) is a substitute for the more expensive sewing machines which have been devised from time to time, and consists of a light metal reel on a framework, which can be attached to most of the needle-holders in common use, or even to a pair of Spencer Wells artery forceps. The reel has deep flanges which are perforated, allowing for thorough sterilisation of its contents. Its axle is instantly unmountable from the frame by the turn of a milled nut on either side. The needle is half-curved with the eye at the point; and, unlike the ordinary variety, once it is in the holder it need not be released. This alone saves some seconds per stitch. The needle is threaded and passed through the tissues in the ordinary way, the free end is then gripped with forceps, and the needle brought back again through the hole made, along the thread, which is then cut between tissues and needle. This is one suture made, and the needle is ready for the next. The *modus operandi* as printed seems longer and more complicated than it actually is, but the process, once seen, is easily understood and acquired. A continuous suture can be adopted with slight modification, while for rapid ligaturing the advantages are obvious. The attachment is cheap, adaptable, simple, efficient, clean, instantly changeable (allowing different materials or sizes to be used), time-saving, and practical. It and its contents need not be touched at all by hand after sterilising. A good all-round material to use on the spool is linen thread.

FIG. 2.

The Holborn Surgical Instrument Co., Limited, Holborn Viaduct, London, E.C., have carried out both these ideas from my models and sketches.

Folkestone. B. RICHARDSON BILLINGS, M.R.C.S. Eng.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The council of the above institute announce that they have accepted the offer of Professor W. R. Smith, M.D., D.L., J.P., to present annually a gold medal of the value of £20, "for conspicuous services rendered to the cause of preventive medicine within the British Empire." It is intended that eligibility for the award shall be confined to medical officers of health or other medical officials—navy, military, or civil—within the British Empire, Overseas Dominions, or spheres of British influence, discharging public health duties connected with the State, and it is proposed that the first award shall be made in 1914.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 1, 1913.

The Royal Commission on the Prevalence and Effects of Venereal Disease.

A Royal Commission has been appointed, in accordance with medical and public expectation, to make an investigation into the whole subject of venereal disease in the United Kingdom, and the terms of reference which follow are almost exactly those which have been anticipated in these columns. They are: "To inquire into the prevalence of venereal diseases in the United Kingdom, their effects upon the health of the community, and the means by which those effects can be alleviated or prevented, it being understood that no return to the policy or provisions of the Contagious Diseases Acts of 1864, 1866, or 1869 is to be regarded as falling within the scope of the inquiry." The *personnel* of the Commission is also in close accordance with information which had been widely disseminated, and the general conclusion formed will be that the arduous and delicate work has been well defined, and that the Commission has been selected for its duties with much judgment. The Commission is formed as follows: Lord SYDENHAM of COMBE, F.R.S. (Chairman), the Right Hon. Sir DAVID BRYNMOR JONES, K.C., M.P., Sir KENELM E. DIGBY, Sir ALMERIC FITZROY, Sir MALCOLM MORRIS, F.R.C.S. Edin., Mr. JAMES ERNEST LANE, F.R.C.S. Eng., Sir JOHN COLLIE, M.D., Dr. ARTHUR NEWSHOLME, Canon J. W. HORSLEY, the Rev. J. SCOTT LIDGETT, D.D., Dr. F. W. MOTT, F.R.S., Mr. PHILIP SNOWDEN, M.P., Mrs. SCHARLIEB, M.D., Mrs. CREIGHTON, and Mrs. BURGWIN. The Secretary of the Commission is Mr. E. R. FORBER, an official of the Local Government Board.

To medical readers the claims of Dr. F. W. MOTT, Sir MALCOLM MORRIS, Mr. ERNEST LANE, Mrs. SCHARLIEB, Dr. ARTHUR NEWSHOLME, and Sir JOHN COLLIE to be chosen by the Crown to conduct an inquiry into syphilis are so obvious that we need waste no space in detailing them. It is sufficient to say that as far as the medical constitution of the Commission is concerned the public and the medical profession may be satisfied that the numerous and difficult questions involved will be investigated in the light of the best clinical, pathological, and statistical experience, reinforced by knowledge of public and institutional affairs. The absence of any member of the Commission able to give first-hand advice upon the conditions in the military and naval services is the only omission which calls for notice. Mrs. BURGWIN will be a valuable addition to the scientific side of the inquiry owing to her experience in the education of the feeble-minded. Canon HORSLEY, Mrs. CREIGHTON, Mr. PHILIP SNOWDEN, and the Rev. J. SCOTT LIDGETT are prominent in various phases of social and religious endeavour; while Sir DAVID BRYNMOR JONES, Sir KENELM DIGBY, and Sir ALMERIC FITZROY represent adequately the legal and official learning and tact that will be required both alike to elicit from the best witnesses essential information, and to frame a report which shall have the merit of meeting the ascertained evils in a way that will commend itself to the Legislature. Lord SYDENHAM, better known as Sir GEORGE SYDENHAM CLARKE, has exactly the record as a public servant of high distinction which fits him to preside over the Commission.

This is a Royal Commission which, although its actual appointment has been due to events of recent occurrence, has been much talked about for many years; and it is generally felt that the time has arrived when the State should interfere as protector of the people in the way indicated by the terms of reference to the Commission. The medical profession is in a position to offer far more practical help than would have been possible only a few years ago, for we possess methods of diagnosis, knowledge of pathology, and instruments of treatment that are all of recent acquisition. It is sincerely to be hoped that a strong and judicious Royal Commission will be able, with only such delay as is imposed upon their work by the need for thoroughness, to advise the country of the extent of the evils which venereal diseases are inflicting upon it, and to propose remedial measures whose practicability will recommend them immediately for incorporation in an Act of Parliament.

The Specific Differences among Bacteria.

ALL new sciences have to pass through a stage of infancy before arriving at maturity—and truism as this may be it is too often forgotten. The science of bacteriology is a new one, and when we look into its progress we become aware that in the course of growth some of its tendencies, like those of every infant, have required emendation and correction. Bacteriology has now emerged from infancy—that at any rate we can say without committing ourselves to any prophecy as to how far it has gone towards maturity; and while in all developing movements it is useful from time to time to take stock of the work accomplished, now is a very convenient date, in the case of bacteriology, to recognise the modifications in our knowledge which have become imperative and to estimate the lines which may in the future be pursued with advantage. It may thus be counted as a real gain when someone who is competent to do so gives us a *résumé* of his mature thoughts on the present position of bacteriology from a broad biological standpoint.

In our present issue we publish the presidential address delivered before the Pathological Section of the Royal Society of Medicine on Oct. 21st by Dr. F. W. ANDREWES on the Nature and Degree of Specific Differences amongst Bacteria. For a considerable number of years he has carried out researches in collaboration with Dr. M. H. GORDON and Dr. T. J. HORDER which have been especially concerned with the various bacteria as different species; not only have these researches been conducted along academic lines, but in many instances they have had a very real practical significance. In the address under notice Dr. ANDREWES pauses in the middle of his researches

to look upon the present situation from an eminence and to sift our knowledge in a way calculated to help the academic no less than the practical worker in the field of bacteriology. Now, species is essentially the term of a naturalist. By it he means a freely interbreeding group of individuals derived from a common ancestry. He recognises and defines what he means by a species according to several criteria—morphological characters, capacity or incapacity for interbreeding, known descent from a common ancestor, and in certain cases geographical distribution. As Dr. ANDREWES points out, the bacteriologist is handicapped in the investigation of the various species of bacteria by the fact that the only one of these criteria available to him is the study of the morphological characters. We feel sure that all bacteriologists will agree with Dr. ANDREWES in his caution that severe criticism is necessary before placing too much reliance in this connexion on such characteristics as pathogenicity, virulence, physiological, chemical, and physical properties of bacteria. At the same time, we are entirely in agreement with him in his defence of the position that a bacteriologist is within his rights when he draws certain conclusions, perhaps of the highest practical importance, from his experiments, whereas those selfsame experiments may lack the necessary comprehensiveness to warrant general deductions of scientific importance being drawn from them to a degree applicable to the study of so complicated a nature as the specific differences amongst bacteria.

As regards the much-discussed question of the identity of the various strains of streptococci and colon group of bacteria, Dr. ANDREWES seems to us to take up a very fair attitude. If we can accept such doctrine as this, he says, that in some bacterial groups (and these groups with which pathologists happen to be particularly concerned) rigid specific limits have actually no existence, we shall gain a good deal. We may, for example, leave off quarrelling as to the specific value of fermentation tests and serological reactions, and bend our minds to doing the best we can with the mass of related forms presented by dominant bacterial genera. Nor is the task of classification by any means a hopeless one if it be approached in the right spirit and with a due apprehension of the real state of affairs. The group of streptococci receives especial consideration, as might have been anticipated from his numerous researches on the subject, and he expresses himself on the subject with no uncertain voice. "I hold them," he says, "to be a labile group from which types are emerging, which can be recognised by suitable methods, but which are at the present day for the most part undeserving of specific rank." With reference to the future, he looks to a chemical solution of many at present baffling problems. The phenomena of agglutination and precipitation of bacteria, to mention only two, are probably chemical or physico-chemical reactions which will receive their true elucidation at the hands of the experimental chemist. All workers in the difficult field of bacteriological research would do well to read carefully Dr. ANDREWES'S lucid exposition of a very complicated subject, and we offer him our thanks for a valuable and stimulating disquisition on bacteria as causative agents of many serious diseases in man.

The Decline of Imprisonment.

IN any moral inquisition, such as is generally regarded as one of the most important functions of statistical inquiry in the modern State, it is natural that a special degree of interest should attach to the statistics of criminality. These statistics seem at first sight to offer a direct and positive measure of the moral health of the community; and the assumption that they have this significance is in fact so commonly made by popular opinion that any considerable oscillation in their movement is usually interpreted without further question as an index of a corresponding change in public morals. In connexion with criminality, however, there is even more need than in the case of other social phenomena to bear in mind the proverbial limitations of statistical evidence, especially when the data with which we are dealing are drawn from a limited area or when they refer wholly or mainly to some single one among the many aspects of this complex question.

It may be useful to recall these qualifying considerations in judging of the real significance of the remarkable decline in the prison population to which attention is specially drawn in the latest annual report of the Commissioners of Prisons and Directors of Convict Prisons. From that report it appears that during the year ended March 31st, 1913, the number of commitments to prison in England and Wales was lower than in any year of which there is statistical record. Moreover, as the Commissioners show by a comparative table giving the numbers of the prison population over a series of years, this shrinkage is not due to any sudden and exceptional causes operative within the last 12 months, but is, on the contrary, a continuation of a downward movement which has been evident throughout the last decade. Obviously this steady diminution in the number of persons sent to gaol is in itself an extremely gratifying fact; and it would, of course, be still more satisfactory if we could infer from it that the moral tone of the community has been improving in anything like the same measure. There are, fortunately, good reasons for thinking that in many respects the standard of conduct prevalent nowadays is very probably higher than it was even in the memory of the present generation, and we may perhaps in an indirect way find support for this view in the falling numbers of the prison population, in the sense that this phenomenon is doubtless evidence of a humaner tendency in society, of a more careful discrimination in its way of dealing with those who fail to conform to its laws. To go farther and to assume that these statistics are proof of a real decrease in delinquency is, however, a very different matter, and is much more than the evidence will warrant. The statistics of imprisonment, it must be remembered, are peculiarly misleading. To a greater extent even than is the case with other statistics of criminality, the oscillations in the numbers of the prison population are affected by fluctuations in economic conditions; for the rise or fall in general prosperity influences not merely the number of offences committed, but also the proportion of these offences which will be compensated by the payment of fines. A year, therefore, of booming trade,

such as last year was in so conspicuous a degree, will ordinarily be a year in which the forms of illegality that are numerically of most importance, such as crimes of acquisitiveness and parasitic offences generally, will be fewest, and in which also the proportion of petty offenders who pay fines will be highest. These two influences, both tending in the same direction, have probably been the most important factors in bringing about the decline in imprisonment. But their effect has certainly been helped by another tendency which the student of sociology will note with interest and approval—the tendency, that is to say, to be more sparing than formerly in the use of this particular mode of punishment. Public opinion has changed considerably within the last few years with regard to the value of imprisonment, more particularly in its application to certain categories of offenders, and in harmony with these newer and better views the law has provided a wider choice of alternative penalties. As a consequence, some classes of offenders have almost ceased to be sent to gaol, and in the case of several other classes imprisonment is merely retained as a violent remedy to be tried only when milder and more appropriate methods have proved unsuccessful. The increasing use of the Probation Act and the establishment of Juvenile Courts under the Children Act may be specially instanced to illustrate this point; these changes in the law have operated powerfully to decrease the number of commitments to prison. And it may be presumed that if the provisions of the Mental Deficiency Act are used as they ought to be in dealing with weak-minded delinquents and drunkards, there will be a further decrease in the population of our gaols, in which these troublesome recidivists have hitherto bulked so largely.

In the main, then, we may take it that the diminution in the prison population, in so far as it is not accounted for by temporary variations in the economic factors of crime, is due to a changed public opinion which no longer regards the gaol as a social panacea. Amongst the influences which have contributed to bring about this saner attitude, one of the most important has been the clearer perception of what should be the true function of imprisonment, a perception which necessarily leads to closer scrutiny of the conditions that determine the effective performance of that function; and on these points our knowledge has been considerably widened of recent years, thanks to the more scientific spirit which has been introduced into the penal administration of this country. The record of Sir EVELYN RUGGLES-BRISE and his colleagues in this work of reform should therefore entitle them to speak authoritatively regarding the application of this method of treatment which they have done so much to render really corrective and reformatory. And they will certainly carry public opinion with them in their demand that the present abuse of imprisonment shall be amended, and that an end shall be made of the futile and pernicious system of repeated short sentences for petty offences. How great is the extent of this evil may be gathered from the Commissioners' statement that of the prisoners received from the ordinary courts during last year no less than 121,126, or 80·6 per cent., of the total number committed were sentenced to terms of one month or under. These amazing figures are certainly sufficient proof that there is need of some statutory alteration of the existing law to prevent the continuance of this useless and mischievous practice; and it is satisfactory to learn from the Commissioners that there is a prospect of legislative action on the matter in the near future.

Annotations.

"Ne quid nimis."

PRESERVATIVE REGULATIONS (MILK AND CREAM).

THE Local Government Board has recently issued a circular in which is given the outcome of consideration by the Board of the question of the manner in which the details of action taken under the Public Health (Milk and Cream) Regulations, 1912, can be most conveniently reported. It may be pointed out that by these Regulations a definite restriction has been placed on the use of preservatives by producers, retailers, and others concerned in the milk and cream trade. No preservative is to be added to milk in any case or to cream which is sold as cream. The Regulations, however, do not prohibit the sale of cream containing borax preservatives or hydrogen peroxide provided (1) that it is sold, not as cream but as preserved cream, and (2) that the vessel in which it is sold bears a declaration, in the prescribed form, setting forth the amount and nature of the preservative added. The addition of any other preservative is prohibited. The Regulations were provided to secure that preserved cream shall be distinguished at all stages of sale from cream to which no preservative has been added, a distinction which is obviously important in the interests of the public, but particularly when the consumer is an infant or invalid. In a circular issued last year the Board suggested that the medical officer of health should be instructed to exercise general supervision over the action taken in pursuance of the Regulations, and that the officer who directs sampling and the analyst should confer with him in regard to the procedure best adapted to secure observance of the Regulations. The Board now considers that it is desirable that medical officers should include a brief statement in their annual reports as to the efficiency of administration on these points. It would be of advantage, of course, to have this statement drawn up under headings which the Board has supplied in a table in the appendix of the circular. It is suggested that the system of control in regard to the use of preservatives can be made more expeditious by the analyst being informed precisely of the reason why the sample has been taken. Thus, on one occasion the only analytical determination required may be the proportion of fat in cream, on another it may be whether a preservative is present, or again, whether the statement on the label as to the nature and amount of added preservative is borne out by analysis. It is hoped that by the adjustment of procedure in this way, and by consultations between the medical officer of health and the analyst, much unnecessary analytical work can be avoided.

SALVARSAN.

IN the present issue of THE LANCET we print a paper on Salvarsan by Sir Malcolm Morris and Dr. Henry MacCormac, which was read in brief at the recent International Medical Congress. It contains a careful study of the use of salvarsan, and to a less extent neosalvarsan, in some 500 cases of syphilis, in each of the three stages of the disease. The conclusions at which the authors have arrived may be briefly

given as follows—that of the two drugs salvarsan is the more active and the more stable, and it is therefore to be preferred; that salvarsan is effective in every stage of syphilis and more rapidly effective than mercury; that while they have had no fatal results in their own practice they are inclined to think that a primary injection is only dangerous when there is some serious lesion present, but that second injections may prove fatal with little obvious cause; that in most of their cases only two injections were given, but that in some as many as seven were administered, but they doubt the efficacy of these numerous doses as they think the spirochætæ become immune to the drug; and, lastly, they consider that though salvarsan has a wonderful action on syphilis, its use should always be combined with the administration of mercury. The paper gives an excellent summary of our present knowledge of this drug, and the information is very timely in view of the appointment this week of a Royal Commission to inquire into the prevalence of venereal diseases, and the means to counteract their effects. We also publish on p. 1290 an appeal from Dr. Dreuw, of Berlin, for information as to fatal results or serious symptoms following the use of salvarsan, which would seem to suggest that all the unfortunate cases do not obtain record.

DIABETES FOLLOWING TUBERCULOSIS.

IT is well known that diabetics frequently succumb to pulmonary tuberculosis, but the converse condition—diabetes following tuberculosis—is very rare. In the *Australasian Medical Gazette* of Sept. 6th Dr. G. E. Rennie has reported the following case. A compositor, aged 23 years, was admitted into the Royal Prince Alfred Hospital, Sydney, on May 25th, 1913, complaining of cough and expectoration of five weeks' duration. He stated that previously he had been quite well. He was somewhat emaciated and anæmic. The temperature was 98° F. and the pulse 104. The upper half of the right chest showed the signs of tuberculous infiltration with cavity formation; the left side showed signs of scattered tubercles. The appetite was poor. The urine was of specific gravity 1015, and did not contain sugar. While in hospital the temperature ranged from 100° to 101°. At first the general condition improved and the expectoration diminished, though he lost weight. On June 22nd he suddenly began to pass a large amount of urine and complained of thirst. On the 23rd he passed 11 pints which contained a small amount of sugar and a trace of acetone. On the 24th he passed 7 pints containing 8·6 per cent. of sugar and a considerable amount of acetone but no diacetic acid or albumin His breathing became shallow and he was very drowsy. He vomited once and was delirious all night. On the 26th he was stuporous, with hurried shallow breathing, and died comatose. The necropsy showed a cavity in the upper lobe of the right lung, not at the apex, but extending out from the root of the lung, with recent extension of peribronchial and perivascular tubercles, and disseminated tubercles in the left lung. There were no tubercles in any other part of the body. The liver was normal. Towards the tail of the pancreas there was an appearance of hæmorrhagic pancreatitis. Microscopic examination of the organ showed much more disease than the macroscopic appearance suggested. The interstitial tissue appeared to be swollen or œdematous with formation of new connective tissue cells, and in places infiltration with polymorph leucocytes. The glandular tissue had lost its regular disposition; the cells were irregular in outline, with badly staining, occasionally vacuolated cytoplasm. The islands of Langerhans were indistinct with reduction in the number of cells; those that remained were small, and their nuclei were shrunken and granular. The ducts showed slight proliferation of the lining epithelium with detachment from the basement membrane. The microscopical appearance generally suggested catarrhal inflammation with profound disorganisation of the glandular tissue. Some sections were stained for microbes, but no tubercle bacilli or other organism were found. Sections of the kidneys showed marked cloudy swelling. Writers agree as to the rarity of glycosuria in pulmonary tuberculosis. Montgomery states that this has been the experience of the Phipps Institute for the Study of Tuberculosis. The report on nearly 32,000 cases of pulmonary tuberculosis in a number of American sanatoriums shows that glycosuria was present in 101 cases and diabetes in 51. However, the exact relation of the two conditions is not given. Montgomery failed to find a definite case of tuberculosis preceding diabetes. Though it has been recognised that diabetes may be a sequel of several infections, such as influenza, diphtheria, and typhoid fever, tuberculosis does not seem to have been mentioned as a predisposing cause. Another noteworthy point in this case was the rapid course of the diabetes; death occurred four days after the onset of the polyuria. The sudden onset of the diabetes suggested extension of the tuberculosis to the brain, but careful post-mortem examination failed to show any signs of this, nor was there any sign of abdominal tuberculosis. The disease of the pancreas was certainly not tuberculous. Tuberculosis of the pancreas is very rare. Dr. Newton Pitt states it is found in about 1 in 2000 necropsies, and in most of the cases the subjects are children with generalised tuberculosis. Carnot[1] investigated the relation of tuberculosis to pancreatic disease and suggested that tuberculous toxins are excreted in the pancreatic juice and cause irritation in this process. He recorded some cases of comparatively young persons in whom fibrosis of the pancreas coincided with tuberculous disease elsewhere.

THE BANE OF SULPHUR IN THE GAS-SUPPLY.

IN spite of the improvements which have been made and which are being prominently brought into public notice just now in regard to the applications of gas to domestic service, there undoubtedly remains one reproach which we are surprised the great gas industry does not seriously concern itself to remove. We refer to the fact that, however completely or satisfactorily gas is burnt, sulphur dioxide or trioxide is a most objectionable constituent of the products of combustion. It is not only a constituent which corrodes metal fittings, attacks books, ceilings, and many domestic appurtenances, but it is also objectionable to the respiratory organs. The admirable burner known as the inverted gas burner has done much to bring gas lighting to a high pitch of excellence and efficiency, but owing to the sulphur in the gas its metallic parts soon corrode and perish. Even when the metal fittings are replaced by porcelain or similar material there is still a destructive action. It would be so much pleasanter if gas could be burned without showing these corrosive effects, if the ceiling did not blacken, if the metal parts of the gas stove did not lose their original attractive tone, if offensive deposits did not collect in and about the initially bright metallic burner; and these troubles would probably be avoided if gas were supplied quite free from sulphur. If the products of combustion were purely carbonic acid gas and water, probably most, if not all, of this mischief would be averted. At one time there was a Parliamentary restriction in regard to the amount of sulphur in gas, the gas companies being required to keep the total sulphur in the gas distributed down to about 20 grains per 100 cubic feet. As a matter of fact, under this requirement the

[1] Thèse de Paris, 1897-98.

companies kept the amount down to 12 grains. In 1906, however, the restriction ceased owing to the increased economical usage of gas, and then the gas supplied frequently contained 48 grains of sulphur per 100 cubic feet. The companies saved money, of course, because the removal of this restriction meant that they could do without a purification process which was expensive or troublesome to carry out. The gas supplied, however, proved so detrimental to the metal work of burners and fittings that to save their own reputation a method of partial purification was again brought into requisition. At the present time, however, London gas contains still an amount of sulphur which cannot be overlooked in view of hygienic, artistic, and economical considerations. It averages about 24½ grains per 100 cubic feet. We are confident in saying that the biggest march forward that the gas companies could make in their own interests and in those of the public would be made by removing the whole of the sulphur impurities of the gas-supply.

GONORRHŒAL ARTHRITIS IN AN INFANT SHOWING NO PRIMARY LESION.

ALTHOUGH arthritis is no uncommon sequel to gonorrhœal infection of the genito-urinary tract in adults, it is a rare complication of ophthalmia neonatorum. Still rarer is gonorrhœal arthritis among infants in whom no primary lesion is demonstrated. Indeed, apart from Holt's and Finkelstein's cases, such a condition would seem to be hitherto scarcely recognised. Dr. Laimi Leidenius in *Finska Laekaresaellskapet's Handligar* for August, 1913, has recorded an example of this condition. A primipara, aged 34, had been well during pregnancy and earlier. Labour lasted 12 hours, and terminated normally without a digital exploration being made. On the third day of the puerperium a bacteriological examination of the lochia showed gonococci. The uterus was somewhat tender; and a temperature ranging from 98·6° to 100·4° F. in the axilla lasted for a couple of weeks during the puerperium. Directly after birth the male infant's eyes were subjected to the routine treatment with a 1 per cent. solution of silver nitrate. On the tenth day the right knee—which was flexed and not easily extended—showed a red, tender, and fluctuating swelling. After the knee had been kept in splints for a day, during which the temperature was normal and the general condition satisfactory, the redness and fluctuation diminished. On the fourteenth day the knee again seemed normal, while the left elbow-joint was red, painful, and swollen, and active and passive movements were much limited. Redness and swelling were also evident in front of the left ear. The rectal temperature, which had risen to 104°, fell in the evening of the same day to 98·6°. On the seventeenth day the elbow-joint had improved, while the right knee showed a relapse, having again become red and swollen. Splints were reapplied, and for the following eight days the temperature ranged between 98·6° and 100·4°. On the twenty-second day exploratory puncture of the knee, elbow, and mandibular joints yielded a watery, greyish-yellow, purulent fluid containing numerous gonococci. The swellings slowly diminished and the general condition improved, the infant being discharged from hospital when six weeks old. The left mandibular joint was now normal, but the joints of the elbow and knee still showed some thickening and limitation of movement. During the six weeks' stay in hospital the infant's weight had risen from 2350 to 2500 grammes. Six months post partum the elbow-joint appeared normal, and after another six months the knee-joint also showed complete recovery. But the right femur was slightly shorter than its fellow. During the infant's stay in hospital the examination of the secretion from the conjunctivæ, mouth, and urethra, and of the mother's and infant's blood, was negative. When gonococci have been demonstrated in the blood of infants there has also been, as a rule, ophthalmia to account for their presence. Holt has recorded four cases of vulvo-vaginitis and urethritis in infants whose blood contained gonococci. He has also given an account of 26 cases of gonorrhœal arthritis, in 18 of which no gonococci could be found in the nose, urethra, or about the eyes. He thinks the primary lesion must have been in the mouth, for many of the infants suffered from stomatitis, and it is probable that the infection was carried from one mouth to the other by the nurses' fingers. Dr. Leidenius excludes the mouth as a source of infection in his case, for it was not washed by the attendants. He also excludes the conjunctivæ and urethra, but he is less certain about the mucous membrane of the nose. Here there was no sign of disease, but it is yet possible that the micro-organisms may have entered the body at this point, where an intact mucous membrane does not prevent the ingress of germs. Unfortunately the solution of silver nitrate was not applied to the nose, the secretion from which was not examined bacteriologically. If this explanation be correct the case is probably unique, for when a generalised gonococcal infection has been accompanied by nasal infection this has been secondary to a primary conjunctivitis. Dr. Leidenius admits, however, that an intra-uterine infection may have occurred through the placenta, and that the infant's immunity during intra-uterine life may have been due to the presence of antibodies, formed in the maternal system and transmitted to the infant. When, however, the supply of these antibodies was cut off at birth, the infant may no longer have been able to combat the infection successfully, and arthritis ensued.

THE LONDON SCHOOL OF TROPICAL MEDICINE.

THE annual dinner of the London School of Tropical Medicine, which was held on Oct. 24th at Princes' Restaurant, under the chairmanship of Dr. F. M. Sandwith, was memorable for a number of reasons. In the first place, Mr. Austen Chamberlain, to whom was most suitably entrusted the toast of the evening, had the satisfaction of announcing that the special appeal fund committee, of which he is chairman, has already received £70,000 out of the £100,000 which they set out to obtain. Mr. Chamberlain was also able to indicate the various purposes to which this fund will be allocated—namely, building extension, a research fund, endowment of the school, and the provision of special treatment for men of small means returning to England suffering from tropical disease. In the next place, the chairman, during the course of his reply, stated that the school now had the largest class of students which it had ever had, and the greatest number of resident students; while he added, amidst much applause, that one of the wards of the hospital was in future to bear the name of the Chamberlain Ward. Thirdly, the dinner itself, which was attended by a distinguished company, including Viscount Milner, Sir West Ridgeway, Sir Pardey Lukis, Surgeon-General A. W. May, Surgeon-General Sir A. M. Branfoot, Sir Havelock Charles, Sir William Leishman, Sir William Bennett, Sir John Rose Bradford, Sir William Treacher, General Sir Reginald Talbot, Mr. Percival Nairne, Sir Francis Lovell, and Mr. P. J. Michelli, was the largest annual gathering in the history of the school. But perhaps the most interesting event of the evening was the presentation to Sir Patrick Manson of two life-like portraits of himself, which were unveiled by Mr. Austen Chamberlain amidst enthusiasm. The presentation was appropriately made on behalf of the subscribers by Mr. James Cantlie and Dr. W. T. Prout, representing the London and the Liverpool Schools of Tropical Medicine respectively, and glowing tributes to Sir Patrick Manson's pioneer work in tropical medicine

and to his personal qualities and public services were made by each of the speakers. It is intended that one of these portraits shall hang at the London School of Tropical Medicine and that the other shall remain in the possession of Sir Patrick and Lady Manson and their family. After Sir Patrick Manson had made acknowledgment of the presentation the toast of "the Guests" was proposed by the chairman and responded to by Sir John Anderson, Permanent Secretary of the Colonial Office, and Dr. Sandwith's health was proposed in warm terms by Lord Milner, who spoke of his long acquaintance with the chairman since their early days together in Egypt. During the course of the dinner messages of good wishes were exchanged by telegraph between the assembled company and Mr. Joseph Chamberlain, to whom the school is greatly indebted.

THE PECULIARITIES OF SENSIBILITY FOUND IN CUTANEOUS AREAS SUPPLIED BY REGENERATING NERVES.

UNDER this title Mr. Wilfred Trotter and Mr. H. Morriston Davies, of University College Hospital, have published in the *Journal für Psychologie und Neurologie* (Band XX., 1913, Erganzungsheft 2) an important communication embodying the results of researches extending over six years. It will be remembered that in 1905 Dr. Henry Head took a great step in advance, in the study of the difficult problems of cutaneous sensibility in man, by submitting to section of a cutaneous nerve in his own person and by investigation of the changes thereafter produced on his own left forearm and hand. Basing his conclusions on the results obtained by this research, Dr. Head formulated a hypothesis of the function of the peripheral nervous system which was entirely novel and proved to be very illuminating. Dr. Head stated that the peripheral nervous system, on the afferent side, was compact of two subsidiary systems, to which he assigned the terms "protopathic" and "epicritic" respectively. Protopathic sensibility was concerned with the appreciation of painful cutaneous stimuli and the extremes of heat and cold. Epicritic sensibility was concerned with cutaneous localisation, the discrimination of two points, and the finer grades of temperature called cool and warm. In view of the extreme importance of the experimental facts established by Dr. Head and the unsatisfactory nature of examinations of ordinary patients, Mr. Trotter and Mr. Davies commenced a series of similar observations on themselves in 1907. The end they had before them was to obtain as wide a field as possible from which to draw material, and by performing more than one experiment on themselves to gain knowledge from the phenomena of one which could be used to amplify and coördinate their methods in the next. Accordingly, at intervals during these six years they have divided the following cutaneous nerves in themselves: the internal saphenous, great auricular, internal cutaneous of arm, a branch of the middle cutaneous of thigh. In each instance a piece of the nerve trunk from 5 to 10 mm. in length was excised and the ends united by sutures. It may be remarked parenthetically that the authors found the amount of inconvenience incident on having a divided cutaneous nerve or two extremely small. From the material thus procured, and as the outcome of a prolonged and rigorous investigation, the authors adduce facts which do not entirely fit in with the theory of Dr. Head, and which, by reason of their cumulative value, are calculated to render the hypothesis of separate epicritic and protopathic systems one the evidence for which is not so unequivocal as may have been supposed. They have found that when a cut nerve is regenerating all forms of sensibility tend to reappear together; that all returning sensibility is at first hypoæsthetic; and that all returning sensibility shows the phenomena of "intensification" and of "peripheral reference." By the former term is meant that the sensations elicited by stimuli are intense out of proportion to the stimuli; by the latter, that when a recovering spot at the proximal end of the anæsthetic area is stimulated, the corresponding sensation, instead of or in addition to being felt locally, is felt at the extreme peripheral end of that area. The important point in these observations is that the authors cannot find any criterion of distinction between the ways in which the various forms of cutaneous sensibility recover, such as Dr. Head found in his one experiment, and on which, to some extent at least, he based his hypothesis of separate physiological systems in the main cutaneous afferent system. There are other facts and other arguments adduced by the authors which need not be further specified, which go to show that the interpretation of the phenomena of regenerating sensibility is simpler than that given by Dr. Head. In the meantime the clinician must be content, we think, to reserve judgment. The exact import of the work here summarised will be seen better when it is put to the test of clinical experience. We consider, however, that Mr. Trotter and Mr. Davies have by this minute and painstaking investigation made no small contribution to the solution of a vexed problem, and have added lustre to the experimental neurology of this country which Dr. Head's researches have already raised to so high a level.

THE PATHOGENESIS OF SYPHILITIC MUSCULAR ATROPHY.

AMONG the many minor though none the less fertile discussions at the recent International Congress of Medicine was one on the question of muscular atrophy in tabes and other syphilitic affections. Various opinions as to its pathogenesis have been held: the varying picture presented by the pathological anatomy of these cases is one reason for this absence of unanimity. Tabetic amyotrophy in some cases is the result of ischæmia of the cord from syphilitic disease of the vessels or of the meninges. Sometimes it appears to be the result of a peripheral neuritis; sometimes there is evidence to suggest a direct action of the syphilitic poison on the nervous parenchyma—i.e., the anterior horn cells. Much light has been thrown upon the syphilitic origin of tabes by the work of Dr. Hideyo Noguchi, who recently gave a demonstration of his results at the Royal Society of Medicine.[1] Dr. A. Barré, of Paris, in his contribution to the discussion said that in certain cases of tabetic amyotrophy important vascular lesions are present, consisting in subacute or chronic endo- and peri-arteritis and in endo- and peri-phlebitis. It would appear that these lesions have hitherto not had much attention directed to them, but Dr. Barré held that some at least of the tabetic amyotrophies are vascular in origin and ischæmic in character, and that from the pathogenic point of view these are closely allied to the other trophic disorders of tabes more frequently met with—viz., arthropathies, perforating ulcers, &c. It is erroneous to regard these trophic changes as tabetic in the strict sense; the vascular modifications are essentially syphilitic, and whereas some have ascribed a preponderating pathogenic rôle to lesions of the intramuscular nerves, Dr. Barré regarded both these and the actual muscular lesions as secondary to the vessel changes. A second hypothesis which he advanced is, in our opinion, more debatable. He thought that the lesions of the anterior cornual cells not infrequently seen in tabetic atrophy might be secondary to the relative muscular immobility and to the functional weakness which result from such muscular troubles. Dr. Barré regarded the

[1] THE LANCET, Oct. 25th, 1913, p. 1187.

lesions of the cells as analogous to those seen in the spinal cord after amputation of the limbs. There are cases of tabetic amyotrophy on record, however, in which there is a widespread general defect of anterior horn cells, in no way localised, such as could only have been produced by the chronic action of a toxic or toxi-infective agent, and cases have been published where with prolonged functional disuse of the muscles little or no changes can be seen in the spinal cells. The contribution of Dr. Barré, nevertheless, is of interest; in his recent *Thèse de Paris* on the subject of tabetic arthropathies the whole question has been discussed by him in a lucid and comprehensive fashion.

THE ALLEGED RITUAL MURDER IN RUSSIA.

TRIALS for murder in which a large part of the evidence for the prosecution is circumstantial seldom fail to present features of medical interest. In this country journalistic discussion of cases which are still *sub judice* is rare, and may sometimes be punishable, but in other lands this is not so, and remarkable instances of non-observance of the rule of silence have been provided by the trial of a Jew for the alleged ritual murder of a Christian boy 12 years of age at Kieff, in South Russia. Without expressing any opinion on the principal question at issue we may remark that the evidence given by one of the medical witnesses for the prosecution is very severely criticised in a signed contribution to an important German weekly, the *Deutsche Medizinische Wochenschrift*. In particular, the critic quotes a number of recognised authorities (Haberda, Thoinot and Lacassagne, Bleuler, Bonhöffer, Boedecker, Forel, Meyer, Wagner von Jauregg and Obersteiner, and finally, the English experts, Pepper, Willcox, and Mercier) all of whom, he says, have resolutely rejected the Russian medical witness's views as to the psychological element in crimes of this type. The witness is also emphatically condemned for describing the crime as a ritual murder, a question which is not a medical but a theological one. In conclusion, the critic states that it is the duty of medical men, both in the interests of humanity and for the credit of their profession, not to allow the medical evidence which has been given for the prosecution to pass without protest.

POST-GRADUATE TRAINING IN PHYSICO-THERAPEUTICS.

THE application of physical forces and agents to therapeutic work is a branch of medical specialism whose scope is widening every day. Electricity in countless forms, radium and its emanations, heat and cold in many guises, are the most conspicuous but not the only forms of physico-therapeutic activity. Facilities for the training of those who would devote themselves to this work have hitherto been sparse and precarious. It is true that some of the various post-graduate schools include courses of instruction therein, but several reasons, of which insufficiency of equipment is perhaps the most important, have prevented any thorough, complete, and satisfactory educational scheme; and those who wish to become proficient in radiotherapy and the like have to pick it up for themselves by a species of practical apprenticeship which takes time and requires peculiar gifts. There is, it may be said, at the present time no institution in London where qualified medical men can receive a special course of instruction in the technique of radiation. Nor are medical students catered for in this respect with anything like the efficiency that their other studies are looked after. The side that is universally neglected is that dealing with the physics of the methods used; and one result at least is that few medical men who use radiations in their practice know enough of their fundamental properties to extend the range of utility or to suggest new work. It seems that there is some prospect of this deficiency being supplied in the new King's College Hospital at Denmark Hill and its school. But it is evident that the possibility cannot mature for some time at least; and meanwhile a suggestion has been put forward that the fine buildings and equipment provided last year at the Cancer Hospital[1] should be utilised to fill the gap. Mr. C. E. S. Phillips, physicist to the department, has proposed the outlines of a scheme for instituting a post-graduate course in radiation technology at the Cancer Hospital. Mr. Phillips has had the advantage of Dr. R. Knox's coöperation; this is of some interest in view of the fact that the latter has been selected to take charge of the radiation department at King's College Hospital. The general post-graduate scheme has been sanctioned by the house committee of the Cancer Hospital. Mr. Phillips proposes that a large basement room in the proposed east extension of the radiotherapeutic buildings of the Cancer Hospital, now allocated for experimental work, should be adapted at small extra cost for a class-room and fitted so as to serve both purposes. Lectures and demonstrations could then be given dealing with the physical properties of radiations as well as with their practical medical applications. The course could be made complete by work in the clinical department. Though the general outline of Mr. Phillips' suggestion has been favourably considered by the authorities of the Cancer Hospital, no details have yet been approved. Should it mature successfully, the thorough equipment possessed by the radiotherapeutic department at the Cancer Hospital must prove an incentive to good teaching, and so render the post-graduate course useful and well attended.

AT the Royal College of Physicians of London the Bradshaw Lecture will be delivered by Professor T. R. Glynn on Tuesday, Nov. 4th, on "Hysteria in some of its Aspects," and the Fitz-Patrick lectures will be delivered by Dr. C. A. Mercier on Thursday, Nov. 6th, and Tuesday, Nov. 11th, on "Astrology in Medicine." These lectures will be given at 5 o'clock at the College, Pall Mall East.

THE inaugural meeting of the Midland Medical Society for the session 1913–14 will be held at the Grand Hotel, Colmore-row, Birmingham, on Thursday evening, Nov. 13th, when Dr. F. W. Mott, F.R.S., will deliver an address on the Degeneration of the Neurone in the Light of Recent Research. The chair will be taken by Dr. H. Willoughby Gardner, the President.

THE death is announced of Dr. H. Franklin Parsons, late of the Medical Department of the Local Government Board, and late President of the Epidemiological Society.

[1] See THE LANCET, Oct. 26th, 1912, p. 1171.

MEDICINE AND THE CHURCH.—The annual service for those engaged in medical work in Brighton and Hove was held at the parish church on Sunday evening, and was attended by a large number of doctors and nurses for whom seats had been reserved. The vicar, the Rev. Canon Hoskyns, in the course of his sermon, said one of the encouraging signs of the present day was that not a few of the leading men in the medical profession were beginning to recognise the fact of great spiritual forces which transcended all mere human knowledge and science, and which were waiting to be summoned to the aid of the medical scientist, in order to contribute to and complete the restoration to health, bodily and spiritually, of those who were under the bondage of dread diseases.

SANITATION IN NORTHERN INDIA: THE PUNJAB CONFERENCE.

(FROM OUR OWN CORRESPONDENT.)

THE Punjab Conference has just concluded at Simla. Thirty-five delegates attended from different parts of the province. The Lieutenant-Governor welcomed the delegates in an eloquent speech, in the course of which he said that the object of convening the conference was to obtain advice as to the most pressing sanitary needs and the most practical means of satisfying them. "A new era of sanitary effort seems to be dawning in India," he continued; "there are signs of increased interest in the subject in the press and among the enlightened of the educated classes. At the present moment, owing to the generosity of the Government of India, the Punjab Government are in the position of being able to spend something over 30 lakhs of rupees on sanitation in the next three years. This sum includes recurring grants to the amount of 5½ lakhs per annum. It is one of the duties of the conference to advise the Government how the money may best be spent. The whole sum may be spent many times over on improving the water-supply and drainage of our towns, but those are only two of the objects which claim attention. Sanitary progress necessitates additional staff. A second Deputy Sanitary Commissioner has been sanctioned. Every large town is to have its health officer and its sanitary inspector, and similarly municipalities shall, it is proposed, employ sanitary inspectors according to their means. All or most of these officers will have to be trained in some way or other, and one of the questions to be discussed related to the courses of training which ought to be prescribed for them. The modern problem of town-planning also finds a place in the programme, and one authority boldly advocates a recognition of the right to tax unearned increments in town sites." The questions to be discussed at the conference, he pointed out, ranged from mere matters of finance and the collection of statistics up to problems which are complicated by infinite possibilities of misunderstanding and misrepresentation. To those who are likely to be discouraged by indifference or hostility he addressed Kipling's vigorous appeal: "Take up the white man's burden," for "sloth and folly" can only be met by education, by popular instruction, lectures, and the erection of model buildings. He then alluded to the fine sanitary conditions Lyallpur had recently laid out on modern lines, and to the remarkable philanthropy for sanitary and educational purposes of many private individuals, and concluded with a plea for sympathy with the weakness and ignorance of our Indian fellow subjects, adding, "There is a vast field available without touching their prejudices save with the solvent of education—a field which is wide enough to absorb all the money we can afford and all the efforts we can put forth for many years to come."

Rural Sanitation.

The Commissioner of the Rawalpindi Division moved that:—

As the sum available for non-recurring expenditure on rural sanitation is so small, Government should be advised to devote it in the disseminating centres and in particular to the improvement of fair grounds, especially in connexion with water-supply.

In the course of the discussion which followed, one speaker said that the money should be spent in selected villages, in paving streets, improving drainage, and repairing wells. Another said the money allotted to rural sanitation should not be devoted to fairs. Money was meant to help villagers who lived in villages all the year round. He urged the construction and protection of wells. The money required for fairs should be found from some other sources. It was finally decided to recommend the provision of model conditions in existing villages.

Sanitary Rates.

The next subject for consideration was the necessity for legislation to enforce sanitation by penalties and to provide for the levy of a rate. Previous correspondence on the subject was read explaining Acts relating to it. The question which the delegates had to consider was whether special legislation was necessary or whether the existing law was sufficient to meet the requirements.

One speaker strongly advocated fresh legislation, submitted a draft Bill to the conference for consideration, and moved the following resolution:—

That it is necessary to legislate for the improvement of village sanitation in the Punjab.

Another member said that the provisions of the existing law were quite sufficient, and if the proper regulations were framed, under Section 56, fresh legislation would not be necessary. It was pointed out that the compulsory measures which were adopted for the prevention of plague when it first broke out in the Punjab were met with the utmost indignation by the people. After a lengthy discussion, in which all the delegates took part, the President put the question whether fresh legislation was necessary. The proposal was negatived by a majority voting against the motion.

The Unearned Increment Question.

After a long discussion the following resolution was adopted on the motion of the President:—

That in the opinion of this conference it is not the case in the Punjab that the obstacles to the expansion of towns arising from difficulties in obtaining building sites in suburban areas are so serious or numerous as to necessitate legislation. That such difficulties in this respect as do exist can be submitted if necessary by action under Section 57 of the Municipal Act (the land acquisition sections), especially if Government is prepared to sanction loans for such purposes under the Local Authorities Loan Act.

It was also resolved:—

That measures should be taken by the Government of India to secure for municipal purposes an adequate proportion of the unearned increment accruing to land-owners in urban areas by reason of the demand for building sites arising thereon.

The Necessity for Legislation on the Lines of the English Housing Act.

After this point had been discussed at length the following resolution was put to the conference:—

That it is desirable that Government should have by law authority to empower in special cases municipal committees to demolish buildings in slum areas and to recover a portion of the cost of compensating the owners of the same from the owners in the vicinity who are likely to derive advantage from the improvement resulting from the demolition.

The votes being declared a tie, it was decided to submit the proceedings to the Government.

The sufficiency of the existing by-laws was next discussed, and the following resolutions were adopted:—

1. That it is desirable to lay down non-enforceable standards for the guidance of local authorities in dealing with applications under Section 189 of the Municipal Act.
2. That it is desirable that the committee should make by-laws under Section 190 of the Municipal Act with the object of enforcing minimum standards of sanitation in the case of new buildings.

Sanitation in Connexion with Schools.

The subject was divided under nine different heads, and the first point considered was the condition of schoolhouses, hostels, and other places where people reside, from the point of view of sanitation.

On the motion of the President the following resolution was adopted:—

In the opinion of the conference it is desirable that a committee, composed of officers of education, sanitary and public works departments, and a member of the Punjab Commission, be appointed to prepare plans of school buildings.

A provisional examination of building plans from the hygienic point of view was next considered. In the course of the discussion a suggestion was made for the appointment of sanitary inspectors specially to prevent overcrowding in schools, while it was also decided to have a resolution which would be obligatory on education authorities to observe in the matter of hygienic conditions of schools. The following resolution was adopted:—

That in the opinion of this conference pressure should be brought by the Education Department on local bodies and other controlling agencies to conform, as far as possible, to the regulations to prevent overcrowding in schools and hostels. That, in their opinion, the allotment of grants in aid should be made conditional on the compliance with such hygienic requirements.

It was also resolved:—

(1) That hygiene should be taught as a practical compulsory subject in training schools; (2) that there should be medical inspection in schools; (3) that the existing provincial medical department should be utilised as far as possible for the inspection of schools, supplemented by such additional medical men provided at the cost of the educational grant for school hygiene by local bodies as may be found necessary.

The Registration of Deaths.

The following motion was adopted :—

It is desirable that municipal committees should utilise their medical and health establishments as far as possible in checking and investigating the causes of death as reported in pursuance of municipal by-laws.

The Sanitary Inspector.

The question of the training and qualifications of second-class health officers was considered, and as the Government will shortly be called upon to appoint or advise the appointment of health officers of this grade in five towns in the Punjab, the question of qualifications was felt to be a most important one. The Government thought these officers should possess: (1) a good general education, (2) tact and energy, (3) a certificate after a course of public health approved by the local Government. The pay proposed was Rs. 150–10–300, and it was thought that good men could be obtained for such a salary, which was more than civil assistant surgeons got. The conference resolved that, apart from the qualifications laid down by Government, the health officer should have a medical qualification. With regard to the qualifications and training of sanitary inspectors, it was held by the conference that before anyone was allowed to call himself a sanitary inspector he should be compelled to go through an approved course of training in sanitary work and pass an examination.

Malaria: its Prevention and Treatment.

The President appealed to the educated members of the Indian community to use their influence in challenging false and misleading doctrines ventilated in the press. The poverty of the people was a contributory cause of this disease, but the main cause was the ignorance of the people about common preventive measures. One constantly heard that Indians had a prejudice against the use of quinine, believing that it had a certain deleterious effect. It would be advantageous if medical men could analyse and explain the cause of that misapprehension.

The Sanitary Commissioner, in the course of a speech on antimalaria societies and similar bodies, said, assuming that they would prove useful, how should they be initiated and constituted? Societies should on no account be official in character, but the movements should be helped by the practical sympathy of Government. He urged the establishment of a national public health society with its head in the capital of the province and branches to spread to all towns and eventually to villages. It might seem at present an improbable dream, but given an earnest desire on the part of the leaders of the Indian community, its realisation was far from impossible, and its powers for good in time might far transcend all the efforts that it was possible for Government to make. It was in the hands of Indians themselves that they must leave this question, for it must be above officialdom, above politics, and be irrespective of religion. The following resolution was adopted :—

That the initiation and formation of antimalaria and similar societies cannot be undertaken by Government. 1. This must be left to the people themselves, or rather their leaders, conducted under whose auspices they should prove of great value. 2. Bodies organised for special services should be invited to exercise their influence in educating their fellow countrymen in ideas of sanitation.

The Health Officer of Lahore read a paper on Malaria, in which he enumerated its evil effects, mental and moral, as well as physical, and its wide range of attack, and summarised the steps which should be taken to carry on a successful campaign against the disease. He insisted on the necessity for an adequate supply of good food and of pure water, for the treatment of wells with permanganate of potash and the closing of old wells, for the proper use of mosquito nets, and for the free provision and distribution of these and of quinine. He also advocated the use of fish for the destruction of mosquito larvæ in the large breeding grounds, the removal of jungle and of all natural harbouring places of the mosquito, and lastly, the formation of antimalarial societies among the people themselves.

The subjects of tuberculosis, plague, and cholera were also topics of debate.

General Discussion.

The following resolutions were adopted :—

That the attention of municipal committees should be earnestly directed to the extreme importance of preparing schemes for town extension when such is likely to occur in order to prevent the reproduction of the congested and insanitary areas which disfigure our towns at present, which is the principal cause of a high death-rate. Such town-planning schemes should be looked upon as a primary necessity of equal importance to drainage and water-supply.

The conference was of opinion that the sanitary inspectors should be under municipal control, and appointed and dismissed by municipal committees; that all appointments should receive sanction of the commissioner of the division; and that commissioners should be required to exercise their powers of sanction and control, with the object of ensuring a flow of promotion in their divisions and of facilitating transfers from one municipal committee to another.

On the motion of the President it was decided to recommend Government to consider special legislation to deal with the adulteration of the milk-supply.

MEDICINE AND THE LAW.

The Employment of Boric Acid in Sausage-making.

AT Devonport recently the magistrates convicted and fined three butchers for selling sausages in which boric acid had been used as a preservative in quantities alleged by the prosecution to be dangerous to health. In the case of W. J. Harris and M. Durbin, who were fined 10*s*., the proportion of boric acid proved to be present was 0·4 per cent., or 28 grains to the pound of sausages, and in that of W. F. Pinches 112 grains to the pound, the last defendant admitting a practice of using 1 oz. to 15 lb. He sought to excuse himself on the ground that an assistant had compounded the sausages upon which the charge was founded, and he was fined £2, with costs. The question of the amount of boric acid likely to prove injurious to the health of the consumer was contested in the case of the first defendants, and valuable expert evidence was given by Professor H. R. Kenwood, medical officer of health of the county of Bedford, Mr. O. Hall, medical officer of health of Devonport, and Mr. T. Pickle, public analyst of Devonport, who were called for the prosecution, Dr. T. Y. Simpson giving evidence for the defence. The existence of some conflict of opinion as to the harmfulness of boric acid in small quantities being acknowledged, Professor Kenwood and Mr. Hall gave the result of experiments tried upon themselves. The former had observed marked effects, headache, loss of appetite, depression and diarrhœa following the taking of 10 grains with food at two meals in each day for three days. He spoke of the comparatively greater effect produced by boric acid in some persons than in others, and pointed out that half a pound of the sausages in question, which would mean three or four, would contain 14 grains of boric acid, and might reasonably be eaten at one meal by an adult. He also indicated 14 grains as the maximum dose laid down in the British Pharmacopœia. Mr. Hall had tried the experiment of taking 14 grains of boric acid, and had produced in himself severe gastric disturbance. He also described an example from his practice before he became medical officer of health, when he had prescribed boric acid in 5-grain doses three times a day, and his patient had complained on the fourth day of symptoms of acute indigestion. He explained to the bench the action of boric acid and the manner in which it would operate in order to produce the symptoms described, mentioning the varying degree of susceptibility which might be expected in different individuals, who might be children or invalids. He spoke of the proportion of 28 grains to a pound of sausages as one likely to prove distinctly injurious to a large proportion of the community. Dr. Simpson, who, as has been stated, gave evidence for the defence, was of the opinion that 28 grains to the pound was not an excessive proportion, and could recall no instance in his own experience of small quantities of boric acid in food proving injurious. The case is one to be observed by medical men on account of the proof which it affords of a practice of using boric acid in injurious quantities in sausage-making, and also in a careless manner, as shown by the defence in the second case mentioned. It is also notable on account of the manner in which the personal observation of the expert witnesses was laid before the court in evidence which the magistrates no doubt found cogent and comprehensible.

The Dangerous Pistol.

At the West London police court recently W. Barrington, a young man stated to be a commercial traveller doing

business in foreign countries, was fined £40 with costs (including the fee of a medical man brought at his request to examine him) for being drunk while carrying loaded firearms. He was fortunate in not being convicted of a more serious offence, for the evidence was to the effect that he placed a pistol against the chest of another early morning visitor to a coffee-stall and threatened to "bore a tunnel through his stomach," and that four chambers of a revolver found on him contained cartridges. The magistrate, no doubt rightly, refused to send the defendant for trial on a charge of attempted murder, but it is easy to see that in such circumstances an armed inebriate may have to pay the penalty for taking life without having any very definite grudge against his victim. Pistols will, however, no doubt continue to be carried with almost as much freedom from legislative interference as pocket knives until some person more important than an ordinary citizen is shot.

Expectorating in Public Places.

It is satisfactory to note that a defendant was recently fined 10*s.* and 3*s.* costs at the Mansion House for infringing a by-law of the District Railway Company by spitting in one of its railway carriages. This was an aggravated case, as the man, who was a passenger between Barking and Blackfriars, expectorated five times during this not very long journey, and was remonstrated with for what he was doing. No doubt those who asked him to discontinue were not reassured by his reply, and did not regard it as extenuation of his selfish and dirty conduct, for he is stated to have excused himself by saying that he was suffering from a "disease of the chest." The company, which is to be congratulated on summoning the offender and securing his conviction, expressed through its solicitor sympathy with the person whom it was constrained to summon in the interests of cleanliness and hygiene. It is to be hoped that this success will encourage it and other companies to future efforts in the same direction and to the practical expression of sympathy with their passengers generally under conditions which are sometimes of a very disagreeable character. Spitting in public vehicles is not so prevalent and obtrusive as it was 10 or 20 years ago, but it still goes on with almost general impunity and in circumstances in which it could be prevented.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8305 births and 4492 deaths were registered during the week ended Saturday, Oct. 25th. The annual rate of mortality in these towns, which had been 13·6, 14·3, and 13·6 per 1000 in the three preceding weeks, further declined to 13·1 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 13·7 per 1000, and coincided with that recorded in London during the same period. Among the several towns the death-rate ranged from 4·4 in Enfield, 4·6 in Ealing, 4·8 in Ilford and in Gillingham, and 5·4 in Darlington, to 17·2 in Burnley and in Salford, 17 4 in West Bromwich, 19·0 in Northampton, 19·3 in South Shields, and 21·4 in Ipswich.

The 4492 deaths from all causes were 179 fewer than the number in the previous week, and included 536 which were referred to the principal epidemic diseases, against 925 and 743 in the two preceding weeks. Of these 536 deaths, 407 resulted from infantile diarrhœal diseases, 38 from diphtheria, 27 from measles, 27 from whooping-cough, 24 from scarlet fever, and 13 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·6, against 2·7 and 2·2 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 730, 769, and 601 in the three preceding weeks, further declined to 407 last week; of this number 107 were registered in London, 33 in Birmingham 25 in Liverpool, 13 in Stoke-on-Trent, 13 in Hull, 12 in Manchester, 8 in West Ham, and 8 in Swansea. The deaths referred to diphtheria, which had increased from 38 to 49 in the four preceding weeks, fell to 38 last week, and included 6 in London, 4 in Portsmouth, 4 in Liverpool, 3 in Birmingham, 3 in Leeds, 2 in Salford, and 2 in Rhondda. The fatal cases of measles, which had been 28, 26, and 25 in the three preceding weeks, were 27 last week; 7 deaths occurred in Sheffield, 6 in Stoke-on-Trent, 2 in West Bromwich, 2 in Liverpool, and 2 in Dewsbury. The deaths attributed to whooping-cough, which had been 32, 39, and 32 in the three preceding weeks, further declined to 27 last week, and included 7 in London, 4 in Liverpool, and 3 in Leeds. The deaths referred to scarlet fever, which had been 14, 23, and 16 in the three preceding weeks, rose to 24 last week; 4 deaths were recorded in London, 2 in Northampton, 2 in Birmingham, and 2 in Liverpool. The fatal cases of enteric fever, which had been 19, 24, and 20 in the three preceding weeks, declined to 13 last week, and included 2 in London, 2 in Manchester, and 2 in Leeds.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily risen from 2112 to 3247 in the seven preceding weeks, had further increased to 3445 on Saturday last; 530 new cases were admitted during the week, against 498, 484, and 575 in the three preceding weeks. These hospitals also contained on Saturday last 1175 cases of diphtheria, 178 of whooping-cough, 77 of enteric fever, and 67 of measles, but not one of small-pox. The 1185 deaths from all causes in London were 39 fewer than the number in the previous week, and were equal to an annual death-rate of 13·7 per 1000. The deaths referred to diseases of the respiratory system, which had been 123, 176, and 151 in the three preceding weeks, rose to 178 last week, but were 62 below the number recorded in the corresponding week of last year.

Of the 4492 deaths from all causes in the 96 towns, 181 were attributed to different forms of violence and 351 were the subject of coroners' inquests. The causes of 39, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, and in 74 other smaller towns. Of the 39 uncertified causes of death, 11 were registered in Birmingham, 7 in Liverpool, 4 in South Shields, 3 in Gateshead, 2 in London, 2 in Blackburn, and 2 in Blackpool.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1167 births and 606 deaths were registered during the week ended Saturday, Oct. 25th. The annual rate of mortality in these towns, which had been 14·5, 14·7, and 13·9 per 1000 in the three preceding weeks, slightly rose to 14·0 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 14·3, against 13·7 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rate last week ranged from 4·4 in Falkirk, 7·8 in Kirkcaldy, and 8·9 in Perth, to 15·6 in Coatbridge, 18·9 in Hamilton, and 19·8 in Dundee.

The 606 deaths from all causes were 6 in excess of the number in the previous week, and included 62 which were referred to the principal epidemic diseases, against numbers declining from 126 to 69 in the six preceding weeks. Of these 62 deaths, 19 resulted from infantile diarrhœal diseases, 12 from measles, 11 from scarlet fever, 11 from diphtheria, 5 from enteric fever, and 4 from whooping-cough, but not one from small-pox. These 62 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·4, against 1·6 per 1000 in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily declined from 96 to 29 in the six preceding weeks, further fell to 19 last week; of this number, 9 were recorded in Glasgow, 2 in Dundee, 2 in Leith, and 2 in Greenock. The deaths attributed to measles, which had been 8, 14, and 14 in the three preceding weeks, fell to 12 last week, and comprised 11 in Glasgow and 1 in Leith. The fatal cases of scarlet fever, which had been 7, 6, and 13 in the three preceding weeks, fell to 11 last week, and included 5 in Glasgow and 3 in Aberdeen. The deaths attributed to diphtheria, which had been 14, 13, and 8 in the three preceding weeks,

rose to 11 last week, and comprised 3 in Glasgow, 3 in Aberdeen, 2 in Edinburgh, 2 in Kirkcaldy, and 1 in Clydebank. The 5 deaths referred to enteric fever, of which 4 occurred in Glasgow and 1 in Edinburgh, were slightly in excess of the average in recent weeks. The 4 fatal cases of whooping-cough were equal to the average in the four preceding weeks, and were all registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 69, 84, and 80 in the three preceding weeks, rose to 92 last week; 18 deaths resulted from various forms of violence, against 23 and 26 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 590 births and 409 deaths were registered during the week ended Saturday, Oct. 25th. The annual rate of mortality in these towns, which had decreased from 21·0 to 16·0 in the four preceding weeks, rose to 17·8 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these Irish towns averaged 17·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 13·7, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 19·0 in Dublin (against 13·7 in London and 14·6 in Glasgow), 15·1 in Belfast, 20·4 in Cork, 11·4 in Londonderry, 10·8 in Limerick, and 30·4 in Waterford, while in the 21 remaining smaller towns the mean annual death-rate was 20·2 per 1000.

The 409 deaths from all causes were 42 in excess of the number in the previous week, and included 52 which were referred to the principal epidemic diseases, against numbers steadily declining from 132 to 61 in the six preceding weeks. Of these 52 deaths, 29 resulted from infantile diarrhœal diseases, 9 from scarlet fever, 7 from whooping-cough, 4 from measles, 2 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 2·3 per 1000; in the 96 large English towns the corresponding rate was 1·6, while in the 16 Scotch towns it did not exceed 1·4 per 1000. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily declined from 111 to 48 in the six preceding weeks, further fell to 29 last week; of this number 16 were recorded in Dublin, 3 in Londonderry, and 2 in Belfast. The deaths referred to scarlet fever, which had been 5, 2, and 4 in the three preceding weeks, rose to 9 last week, and comprised 7 in Belfast and 2 in Clonmel. The 7 fatal cases of whooping-cough were 4 in excess of the average in the three preceding weeks, and were all registered in Galway. Of the 4 deaths attributed to measles, 2 occurred in Dublin and 2 in Belfast. The 2 fatal cases of diphtheria were registered in Belfast and Clonmel respectively, and that of enteric fever in Dublin. In addition to the above deaths, a fatal case of typhus was recorded in Dublin.

The deaths referred to diseases of the respiratory system, which had been 34, 54, and 48 in the three preceding weeks, rose to 53 in the week under notice. Of the 409 deaths from all causes, 139, or 34 per cent., occurred in public institutions, and 7 resulted from various forms of violence. The causes of 20, or 4·9 per cent. of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeons: P. D. Ramsey to the *Pembroke*, for Royal Naval Barracks; D. G. Addison-Scott to the *Ringdove;* J. H. McDowall to the *Powerful;* and W. N. L. Cherry to the *Diamond*, on completing. Surgeon: S. F. Dudley to the *President*, additional, for the *Maine*.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants are confirmed in their rank:—Edmund T. Burke, Thomas I. Dun, Thomas J. Kelly, and John F. Meenan.

Colonel G. D. Hunter, D.S.O., has embarked for a tour of service in India, and on arrival will be appointed Assistant Director of Medical Services.

Lieutenant-Colonel A. A. Sutton, D.S.O., has taken over command of the Royal Army Medical Corps Depôt at Aldershot. Lieutenant-Colonel C. W. R. Healey, on arrival home, tour expired, from the Military Hospital at Nasirabad Cantonment, has been appointed to the Medical Staff of the London District Recruiting area. Lieutenant-Colonel T. B. Winter, senior medical officer at the Military Hospital, Colchester, has been granted leave of absence. Lieutenant-Colonel G. G. Adams has taken over charge of the Military Hospital at Secunderabad Cantonment. Lieutenant-Colonel H. D. Rowan has been appointed to hold charge of King George V. Military Hospital at Arbor Hill, Dublin. Lieutenant-Colonel H. N. Thompson, D.S.O., has been granted six months' leave of absence home from India. Lieutenant-Colonel R. Holyoake, at present holding charge of the Military Hospital at Sheerness, has been placed under orders to embark at Southampton on Feb. 18th for a tour of service with the Southern Army in India, and on arrival will be appointed for duty with the Fifth (Mhow) Division.

Major F. J. Brankenridge has been appointed to the Oxford University Contingent of the Officers Training Corps. Major W. G. Beyts has taken up duty at Roorkee. Major R. L. Argles has embarked for a tour of service in India. Major A. F. Carlyon has been granted leave of absence home from Mauritius on medical certificate. Major R. L. Popham has been placed under orders to embark for a tour of service with the First (Peshawar) Division of the Northern Army in India. Major E. E. Powell has joined the Aldershot District. Major R. C. Wilson has been appointed Specialist in Radiography at the Military Hospital, Gibraltar. Major W. S. Harrison has been placed under orders to embark for a tour of service in Jamaica in December next. Major C. F. Wanhill has taken up duty at Mhow Cantonment as Specialist Sanitary Officer. Major J. M. Sloan has joined at Quetta. Major B. Watts has been appointed to Meerut Cantonment. Major G. W. Tate has been selected for promotion to the rank of Lieutenant-Colonel, in succession to Lieutenant-Colonel J. Ritchie, deceased. Major S. F. Clark has been appointed Medical Inspector of Recruits to the Western Command. Major W. M. H. Spiller has been detailed for a tour of duty with the Eighth (Lucknow) Division in India. Major J. A. Hennessy has taken over charge of the Military Hospital at Ahmednagar.

Captain R. H. L. Cordner has been appointed to hold medical charge of the Royal Flying Corps at Aldershot. Captain K. Comyn has taken over charge of the Pathological Laboratory at the Military Hospital, Gibraltar. Captain A. S. Cane has been appointed Specialist in Dermatology at Kirkee Cantonment. Captain G. G. Tabuteau has been appointed to the Military Hospital at Cork. Captain F. W. M. Cunningham has been transferred from the Military Hospital at Sialkot Cantonment to Kalabagh, Murree Hills District. Captain M. D. Ahern has been appointed to hold charge of the Military Hospital at Watford, Bermuda. Captain J. H. Graham has been appointed to the Military Hospital at Cosham. Captain A. W. Bevis has been transferred from Baltray Camp to the Military Hospital at Belfast. Captain S. C. Bowle has been appointed to hold charge of the Military Hospital at Newbridge. Captain W. Benson has been appointed to the Military Hospital at Woolwich. Captain C. L. Franklin has been transferred from the Military Hospital at Harrismith to Potchefstroom. Captain G. E. Cathcart has been appointed Staff-Surgeon at Headquarters of the Jubbulpore Brigade. Captain W. Browne has joined at Poona. Captain G. E. Ferguson has been appointed to the Military Hospital at York. Captain J. M. B. Rahilly has been appointed Specialist in Operative Surgery. Captain H. F. Joynt has been transferred from the Military Hospital at Bloemfontein to Wynberg. Captain M. B. H. Richie has been placed in medical charge on board the transport s.s. *Dongola*, which left Bombay for Southampton on Oct. 22nd with time-expired troops. Captain C. E. W. S. Fawcett has been appointed to the Military Hospital at Cork. Captain C. M. Finny has been transferred from the Murree Hills District to the Military Hospital at Barian Cantonment. Captain R. E. Humfrey has been selected for appointment as Specialist in State Medicine. Captain D. Reynolds has

been transferred from the Military Hospital at Rawal Pindi Cantonment to Sialkot. Captain R. P. Lewis has been selected for appointment as Specialist in Physical Training. Captain E. L. Moss has been appointed to the Military Hospital at Tidworth, Salisbury Plain. Captain W. T. Graham has been transferred from the Military Hospital at Multan Cantonment to Calcutta. Captain T. Scatchard has been selected for appointment as Specialist in Dermatology and Venereal Diseases. Captain G. W. W. Ware has been appointed to the Military Hospital at Youghal. Captain R. Davidson has been transferred from the Military Hospital at Woolwich to Hounslow. Captain T. S. Blackwell has been appointed to the Military Hospital at Colchester.

Lieutenants G. Wilson and J. D. Kidd have been appointed to the Military Hospital at Secunderabad to undergo the special courses in Indian Sanitation and Hygiene. Lieutenant N. T. Whitehead has joined the Royal Army Medical College at Millbank. Lieutenant H. G. Monteith has taken up duty at the Military Hospital, Hong-Kong. Lieutenant J. H. M. Frobisher, at present attached to the Military Hospital at York, has been placed under orders to embark for a tour of service with the Northern Army in India, and on arrival will be appointed to the Eighth (Lucknow) Division for duty. Lieutenant F. S. Tamplin has taken up duty at the Military Hospital, Gibraltar. Lieutenant J. S. Levack has been selected to hold charge of the Cantonment Hospital at Nowshera. Lieutenant J. E. Hepper has joined at Bulford Camp, Salisbury Plain. The following officers have been placed under orders to proceed to India for a tour of service during the ensuing trooping season: Lieutenants D. T. Richardson, C. M. Ingoldby, P. A. With, S. J. Barry, and H. W. L. Allott. Lieutenant W. F. Christie has joined for duty in the Straits Settlements. Lieutenant W. J. Webster has been appointed for a tour of service at Malta. Lieutenant E. W. Wade has joined the Military Hospital at the Curragh. Lieutenant C. D. K. Seaver has been appointed to the Military Hospital at Dalhousie Cantonment.

INDIAN MEDICAL SERVICE.

Colonel R. M. Campbell, C.B., C.I.E., Inspector-General of Civil Hospitals and Prisons and Sanitary Commissioner in Assam, has been granted 16 months' leave of absence home from India, pending retirement.

Lieutenant-Colonel A. Buchanan, civil surgeon at Nagpur, has been transferred to Saugor and appointed Civil Surgeon. Lieutenant-Colonel S. H. Burnett has been appointed to officiate as Presidency Surgeon in the Second District of Bombay and to hold medical charge of the Common Prison and Byculla Schools. Lieutenant-Colonel W. Molesworth has been granted three and a half months' extension of leave of absence home from India.

Major P. F. Chapman, on return to India from leave of absence home, has been appointed to hold civil medical charge at Nagpur. Major V. H. Roberts, officiating civil surgeon in the Seoni District, has been appointed to hold civil medical charge of the Chanda District. Major N. R. J. Rainier, civil surgeon at Saugor, has been granted two years' leave of absence combined with furlough home from India. Major W. Liston has been granted an extension of leave of absence home from India. Major N. P. O'G. Lalor, on completion of special duty in connexion with the prevention of malarial fevers, has been appointed Deputy Sanitary Commissioner to the Government of Burma. Major W. A. Justice has arrived home on leave of absence from India.

Captain W. J. Fraser has been appointed for general duty in the Chhindwara District on the termination of special duty at the Central Research Institute of India at Kasauli. The services of Captain H. P. Cook have been placed at the disposal of the Education Department of the Government of India for employment on special duty in the United Provinces of Agra and Oudh. Captain H. C. Buckley, officiating civil surgeon at Muttra, has been granted three months' privilege leave of absence. Captain J. H. Murray has taken up duty as Officiating Superintendent of the Female Jail at Port Blair. Captain R. S. Kennedy has been appointed Medical Officer to the North-East Frontier Police. The services of Captain D. S. A. O'Keefe have been placed permanently at the disposal of the Government of Madras Presidency. Captain M. A. Nicholson has been appointed to be medical officer at the Lawrence Military Asylum, Sanawar, in succession to Captain N. S. Simpson. Captain J. M. A. Macmillan has taken up duty as Officiating Civil Surgeon at Hoshangabad. Captain G. G. James has been granted leave of absence for three months. Captain J. Cunningham has joined at Simla. The services of Captain A. M. Jukes have been placed permanently at the disposal of the Government of Bengal for employment in the Sanitary Department.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Sanitary Service.—Thomas Evan Francis to be Captain, whose services will be available on mobilisation (dated Sept. 1st, 1913).

Attached to Units other than Medical Units.—Lieutenant Lionel D. Bailey to be Captain (dated August 4th, 1913).

Supernumerary for Service with the Officers Training Corps.—Patrick Nicol to be Lieutenant, for service with the Aberdeen University Contingent, Senior Division, Officers Training Corps (dated Sept. 29th, 1913).

THE COURSE OF INSTRUCTION AT HASLAR.

The course of instruction of the newly entered acting surgeons at Haslar was brought to a close on Oct. 17th by the distribution of prizes and commissions by Lady Meux, wife of Admiral the Hon. Sir Hedworth Meux, Commander-in-Chief, Portsmouth. The distribution ceremony took place in the museum of the hospital in the presence of a large assembly of relatives and friends. Surgeon-General J. J. Dennis, R.N., presented the following report:—The grand total of the marks obtained on this occasion includes those first obtained at the examination on entry; secondly, those obtained at Greenwich; and thirdly, those obtained at Haslar. One of the three Admiralty group prizes is awarded for the group of subjects studied at Greenwich, and the remaining two for the subjects studied at Haslar. Special commendations are as follows:—Acting Surgeon G. F. B. Page for obtaining highest marks at both the Greenwich and Haslar examinations and for being first in the Greenwich and one of the Haslar groups, though by the regulations taking only one prize; Acting Surgeon A. M. Henry for being first in the second Haslar group; Acting Surgeon F. C. Wright, for being second in the second Haslar group, and for the consistently good work he has done throughout the examinations; Acting Surgeons Henry and Page for the zeal and ability they have shown in the performance of their ward duties. In the examinations all the Acting Surgeons succeeded in obtaining pass marks, and in the majority of instances by a substantial margin. The gold medal has been gained by Acting Surgeon A. M. Henry, formerly of Guy's Hospital, who obtained the highest aggregate marks in the London, Greenwich, and Haslar examinations. The silver medal has been gained by Acting Surgeon G. F. B. Page, formerly of Edinburgh University, who takes second place. The group prize for the subjects in which instruction is given at Greenwich has also been awarded to Acting Surgeon G. F. B. Page.

The prizes for the subjects in which instruction is given at Haslar are awarded as follows:—

Group 1. Acting Surgeon A. M. Henry, of Guy's Hospital.
Group 2. Acting Surgeon F. C. Wright, of St. Bartholomew's Hospital.

The order of seniority as determined by the sum of the marks obtained by each Acting Surgeon at the London, Greenwich, and Haslar examinations is as follows:—

	Marks.		Marks.
A. M. Henry	3810	D. G. Arthur	3173
G. F. B. Page	3669	A. Simpson	3133
P. L. Gibson	3266	H. E. Y. White	3113
A. J. Patterson	3238	M. Meehan	2984
W. A. S. Duck	3216	D. P. H. Pearson	2966
F. C. Wright	3211	I. S. Cape	2892
B. E. P. Sayers	3195	A. J. Tozer	2731

THE GLAMORGAN RED CROSS GAZETTE.

The Glamorgan Red Cross Officers' Association are to be congratulated on having produced a little magazine which, to quote the words of the editorial introduction, "ought to form a convenient link between the 1800 men and women of our country who, moved by a spirit of patriotism, are spending thought, energy, time, and money to make themselves more useful citizens by becoming effective members of a voluntary aid detachment." It is intended that this publication, which for the present will be published three times a year, the yearly subscription being 6*d.*, 4*d.* for the present year if paid in advance, shall deal with all matters concerning the voluntary aid movement. The present issue contains among other interesting features a letter from Lady

Plymouth expressing the hope that the *Gazette* will develop into a national organ of the movement for Wales, an article on the Development of Red Cross Voluntary Aid Work by Lieutenant-Colonel A. W. Sheen, R.A.M.C.(T.), and the commencement of what promises to be an interesting and useful description of wounds, how and why they heal, by Major R. J. R. C. Simons, R.A.M.C.(T.). The *Gazette* is published by Mr. E. J. Llewellin, Cadoxton, Barry, Cardiff.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1215.*)

XXV.—CHESTERFIELD: COMPETITION AGAINST THE PANEL MEDICAL MEN.

CHESTERFIELD is one of those towns where there is much to gain and but little to lose by going on the panel, as is shown by the fact that every practitioner found it to his advantage to do so. Not only have all the practitioners joined the panel, but some of them think that it will improve the scientific status of the profession, a view which is at variance with what is very usually expressed. The explanation, however, is simple. Where private practice becomes contract practice under the Act there the danger of degradation is obvious, but where club practice—especially the very poor and miserable club practice that prevailed at Chesterfield—is replaced by the panel system and the payment is higher, the tendency should be, and often is, to improve the character of the practice in its scientific aspect. Thus formerly—and notably at Chesterfield—it often happened that no record of any sort was kept. When a patient attended he might possibly be recognised as having been before, but there was nothing to recall what he suffered from or what treatment he had received. Now a record has to be kept, and the panel medical man, unlike his club predecessor, really does know something about his patients. Further, he must form a conclusion and state in writing what he thinks is the matter. Formerly a patient was not even examined till he was so ill as to be able to claim sick allowance from his club. When he was well enough to attend at the surgery and to go to his work a bottle of medicine was given him, and that was all. This was guess-work and not scientific practice. Now with the more precise records that have to be kept under the Act greater care is displayed.

Public Medical Service and Private Medical Aid.

The population of the borough of Chesterfield is estimated at 37,000, consisting mainly of colliers and of men employed in iron and engineering works and hardware potteries. There is also the firm of Robinson, a widely known lint and pill box factory, where a considerable number of women and girls are engaged. The greater part of these women as well as the men belonged to clubs or Friendly Societies before the passing of the Act. Some only paid 2*s.* 6*d.*, others 3*s.* a year for medical aid; the highest given was 1*d.* a week, or 4*s.* 4*d.* a year, but in the majority of cases the sum was less than this. Some years ago the Midland Medical Union took steps in this matter. This body was one of those small but vigorous fighting unions that existed in various parts of England before they were absorbed by the British Medical Association, so that its constitution was altered. This union took the initiative and started at Chesterfield a Public Medical Service, of which Dr. R. A. McCrea is now the secretary and principal organiser. Its institution was the more necessary as, in accordance with the lead taken by the Midland Medical Union some ten years ago, the practitioners of Chesterfield made a united demand that the clubs should pay for contract work 5*s.* a year. This led to a countermove on the part of the clubs which has a very important bearing on the present crisis in the working of the Insurance Act at Chesterfield. Some of the Friendly Societies and clubs amalgamated to form the Chesterfield District Medical Association. As in many instances the amount paid for medical aid was only 2*s.* 6*d.* a year, the demand for 5*s.* a year came as a shock, and the clubs were eager to amalgamate so as to offer a better resistance, and they sought to get out of the difficulty in the usual way—namely, by employing at fixed salaries whole-time men. In this manner two medical practitioners were imported, in spite of the efforts made by the organised medical profession.

A District Medical Association Competing Against Panel Medical Men.

When the Insurance Act came into force this amalgamation of Friendly Societies and medical aid clubs had a great opportunity of which it took full advantage. Coming under Section 15, Clause 4, of the Insurance Act the Chesterfield District Medical Association, as the amalgamation is called, immediately sought to recruit as many insured members as possible. In this they are accused of having resorted to means that are not in keeping with medical etiquette, and by so doing of instituting a system of unfair competition against the medical man on the panel, whose services are replaced by the whole-time salaried doctors in the employ of the District Medical Association.

Among the first steps taken was an attempt to gather together all the money collectors or agents of the insurance companies and clubs. The accusation now is that these agents were offered 6*d.* for every person they could persuade to join the association instead of inscribing their names on the list of a medical man on the panel. There are, I was assured, two sworn affidavits to this effect, and the question arises whether this was not a form of canvassing. The canvasser could say that as the Medical Association, the shorter name given to the amalgamation of clubs, is allowed to do its own dispensing, the patients would be saved the trouble of going to a chemist. These agents spend their lives visiting poor families and collect weekly payments made for all kinds of purposes. They are well known and have considerable influence over the poorer and more ignorant sections of the community. But they have been taught to use the phrase "Personally I should advise you to," for this is not considered canvassing. They must not speak on behalf of, or as the representative of, an organisation that provides medical aid, but as private individuals, and acting on their own responsibility, they may give any advice they choose. It will easily be seen that in actual practice this is a change without a difference. The collector visits every week; he asks, for instance, a poor woman if her husband has selected a medical man, and if not she will probably give the red card to the canvasser who enrols the man in the books of the Medical Association, and thus the medical men on the panel are deprived of patients. Further, the town was placarded with the announcement that the association was approved under the National Insurance. Now it has acquired extensive premises just by the Central Market, and here there are announcements whose professional propriety is open to question.

Sweating Medical Men.

When the executive committee of this Medical Association met to discuss the advisability of taking these premises the president of the association stated that it had now more than 4000 insured persons on the books, and estimated the wives and children of the insured persons who were also members of the association as exceeding 2000. Altogether this body has about 7000 members out of a population of 37,000, which removes a great many patients from the medical men on the panel. To attend to these 7000 persons the association employs only two full-time medical officers, though it is seeking, but so far has failed, to employ as its servant a third medical officer. No one knows positively what salary these two medical officers are paid, but it is quite certain that they do the insurance work at less than the insurance pay, and are therefore sweated. Every quarter this association holds a meeting, and speeches are made pointing out what a fine institution it is, and this is a sort of advertisement. Then a large number of Friendly Society committees communicated to their members that they had decided in favour of the medical officers employed by the association, and many members believed that they had no right to go to the panel medical men. This was absolutely wrong, but the result was an increase of membership for the association, where there were already far too many members considering that there are only two medical officers. Thus the Act, instead of putting an end to the abuses that existed under the old club system, allows in this instance the same conditions to grow up again and with increased intensity.

The Government Concession to Approved Institutions.

To-day, however, matters have drifted from bad to worse. Instead of pulling up sharply the Chesterfield District Medical Association for thus reviving some of the former and worse abuses, it has recently received from the authorities marked and material encouragement. It has always been difficult to deal with the Act apart from politics, but in the present instance this difficulty is naturally and greatly accentuated by the fact that the concessions were made just before the Chesterfield election. Previous to these concessions, approved institutions that provided medical attendance before the passing of the Act could only obtain from the Insurance Committee what they could prove had been spent on each individual member. Thus formerly, if the average cost was 5*s.* a year for all the members, whether insured under the Act or not so insured, the Insurance Committee only gave 5*s.* a head for each of the insured persons who were under the Act. Now Mr. Masterman received on June 4th last a deputation representing the Chesterfield District Medical Association, and in reply issued during the second week in August a memorandum allowing the Insurance Committees to give to approved institutions the full 9*s.* a head "for every insured person who selects the institution to provide his medical treatment, upon the principal officer signing a statement that the average of 9*s.* per head has been expended in respect of insured persons for medical treatment (including the provision of drugs) and general establishment charges; treatment to be not inferior to that given by doctors on the panel." This places in the hands of a private association, managed by a lay committee, where there is no medical control, all the money collected by the State, and partially contributed by the State, for medical purposes.

Protests Against the Memorandum.

It is stated, in response to the objections raised, that it is only intended to place institutions on a level with the panel. But this is hardly satisfactory to the many who think such institutions should not be allowed to exist at all. However, they do exist, but modifications of the Act should tend to check and not to extend the abuses, such as the sweating of medical men, to which these institutions are so likely to give rise. It is all very well to say that the 9*s.* are to be expended in providing medical treatment, but what is the medical attendant himself to get out of the 9*s.*? The Government in any case should be careful not to do these things just before an election. As it is, several medical men protested energetically in my presence. They wanted to know whether every time a Liberal seat is in danger Friendly Societies are to get more money for their own purposes, and this at the expense of the panel medical men and the profession generally. If so they promised that difficulties would arise, seeing that the profession was better organised now and would know how to make its influence felt.

Dealing with the details of the memorandum, the idea that the mere signature of an official belonging to an approved institution was a sufficient guarantee that the whole of the 9*s.* allowed would really be spent only on persons insured under the Act was considered absolutely absurd. A proper balance sheet may be insisted upon, but as yet it is not known that anything of the sort will be forthcoming. Even then, and should the medical officers obtain the full 7*s.* out of the 9*s.*, they will be forced on the strength of this payment to attend to women, children, and other members of the association who are not insured under the Act. For the latter portion of their work they might be paid but little or even nothing. Thus, in fact, if not in form, some of the money paid for persons insured under the Act would help to procure medical treatment for members of the association who were not so insured. The medical profession is now inquiring whether the Chesterfield election demonstrates that the Government can be squeezed when there is a by-election and induced to make concessions to the voting powers of Friendly Societies. Very strong representations have been made to the Government by authori-ed representatives of the British medical profession. Such action, as it affects Chesterfield, weakens the position of the panel medical men, and this, too, in a town where all the general practitioners were willing to go on the panel. To encourage competition against them is hardly a fitting way to reward their readiness to carry out the Act.

Unfair Competition and Increase of Work.

One cause of great complaint is the unfairness of allowing institutions, such as the Chesterfield District Medical Association, the right to dispense for all their patients whether within the mile limit or not. This to many insured persons is a great attraction, as it saves them time. On the other hand, many panel medical men have been in the habit of dispensing, some even keep a qualified dispenser, and have a good stock of drugs. But the Insurance Act puts difficulties here in the way of the panel medical man. Then, when the panel medical man does not dispense and the institution does dispense, the former, of course, does not canvass or tout in any way. But all who have lived in industrial centres know something of the considerable influence exercised by the insurance agents who all day long and every day are in and out of the houses of the poorer classes. These agents may have been told not to canvass but they may, as already explained, give advice on their own personal responsibility. There is nothing of this sort on the side of the panel or in the attempt to help the Chesterfield Public Medical Service. This organisation being started by the members of the profession is obliged to observe medical etiquette, and is therefore put at a very great disadvantage when competing with an institution run mainly on commercial lines. The Public Medical Service is an attempt to solve the problem of medical service for the dependents of insured persons and deserves every support; but it cannot compete against methods of advertising and canvassing, whether these be open or disguised. Therefore, the membership of the Public Medical Service has only increased slowly. But it allows clubs to join in a body, and they all have free choice of medical attendant. Practically all the panel medical men are also on the Public Medical Service. The policy of this service is to give adequate treatment for adequate payment, and the quality of their treatment is absolutely their only advertisement.

The proportion of persons seeking medical advice has considerably increased since the passing of the Act, especially in regard to farm workers, domestic servants, women workers, and especially charwomen. That a good deal of this practice is the result of the facilities now enjoyed by the people is proved by the fact that it does not exist where the facilities are not so great. On this question a general practitioner, living in the outskirts of Chesterfield, was able to give me his own figures for the last six months and dating from April 1st. During that time he had 600 insured persons on his list, for whom he received 2*s.* each extra annually, because he had to supply drugs and they lived beyond the mile radius from his surgery. Of these 193 required medical advice during the six months. But within the one mile radius, an easy distance so that it was not much trouble for the patient to attend at the surgery, no less than 237 patients sought advice out of a rather smaller list—namely, 550 insured persons.

(*To be continued.*)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Salford Royal Hospital and its Work.

AT the annual meeting of the Salford Royal Hospital it was announced that the gift of £5000 promised by the president if a balance of £5500 required to clear off the deficit on the extension of the hospital could be collected during the year had more than attained its object. It was agreed to open the 34 beds remaining empty, so that the total number of beds in future will be 208. Nearly 30,000 patients were treated at the hospital and at the Pendleton Dispensary during the year. The deficit on the year's working was £2212.

An Estate and Sanatorium for Stockport.

The Stockport town council, on the recommendation of the health committee, has decided to purchase the Woodville estate, Reddish, in order to provide hospital accommodation for consumptive patients. The cost of the estate will be £6500, and comprises about 20 acres of land and a large mansion which will accommodate from 36 to 40 patients. The

hospital will be used for consumptive persons who are practically incurable and who would prove a source of infection if left in their own homes. There will also be erected inexpensive shelters for cases under observation and mild cases which have not got to a stage for sanatorium treatment. Stockport and Heaton Norris together have 46,000 insured persons. During the last year there were 250 cases of tuberculosis in Stockport and about 135 deaths from the disease. Nearly 2000 consumptives died during the last decade.

The Smoke Fiend and the Smoke Abatement League.

The annual meeting of the Manchester and District Branch of the Smoke Abatement League was held in Manchester last week, when Lord Newton presided. The aims of the society are first to induce manufacturers to abate the nuisance of smoke from their chimneys, and secondly to stimulate the local authorities to use the powers they already possess for putting down the smoke evil. Out of 139 firms whose chimneys were reported by the inspector 19 had made or were making alterations in their plant. The progress, however, is very slow. It appears that the factory chimneys in Manchester are in a fairly good state, but an excessive quantity of smoke is emitted from chimneys in the surrounding districts. The smoke from domestic chimneys in Manchester is now very much less than it was some years ago, mainly owing to the substitution and use of gas fires and gas cookers, of which over 100,000 are now in use in the city. According to Lord Newton, a person who never left Manchester never saw the sun shine as it might, never knew the real colour of a tree trunk, and probably went to his grave convinced that all sheep were born black. His lordship said that any Bill promoted by the League should be introduced in the House of Lords, where a measure brought forward by a private Member was, at all events, discussed on its merits. He approved as an admirable suggestion the appointment of a Royal Commission to consider the smoke question. Lord Newton offered to introduce in the House of Lords any Bill framed by the League.

Oct. 28th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University: the Report of the General Council on an Inclusive Fee in Medicine.

IN the half yearly report of the General Council of the University of Edinburgh recently issued, Principal Laurie says that from the University point of view the obvious objection to the inclusive fee in medicine was the condition of uniformity which would make it very difficult in the future for any University to increase its inclusive fee in any department, as it would be necessary to persuade the other Universities to agree to the same. It was evidently the intention of those who have been responsible for this principle of the inclusive fee that the fees of the Universities should not be further extended. In the situation created by the establishment of an inclusive fee, any future additions to the Universities in the way of endowments for new chairs, or capital sums for the equipping of new laboratories, must form a source not of gain, but of serious embarrassment. A fresh source of revenue must be found for the Universities, which must be capable of expansion from year to year in order to meet the increasing demands upon the general University fund. Dr. T. Shennan had said that it was evident that the extramural school has played an important part in establishing the Edinburgh Medical School, and was still a prominent factor in maintaining its position. If an inclusive fee in medicine were established it would tend to result in students taking all their classes within the University, and the extramural school would thus, for practical purposes, cease to exist. Further, the supply of trained teachers, which has been so well met in the past by this school, would to a great extent cease. This report will be considered at a meeting of the General Council on Oct. 31st.

The Falling Birth-rate: Meeting in Edinburgh.

A paper on the Birth-rate Commission, by the Rev. James Marchant, director and secretary of the National Council of Public Morals, was discussed at the Conference on Public Morals held in Edinburgh on Oct. 21st. In the course of the paper Mr. Marchant stated that the council had established a private commission of inquiry into the declining birth-rate, composed of leading representatives of religion, science, sociology, literature, and education. It was significant, he said, that a Parliamentary Committee had been appointed in France to inquire into the national, social, and fiscal aspects of their declining birth-rate. These two commissions should elicit facts of which they might truly say that the sooner they were faced the better. Dr. J. W. Ballantyne, of Edinburgh, who opened the discussion, remarked that Edinburgh and Bradford were the two cities which were either rejoicing in or deploring the lowest birth-rate at present, and this fall, as shown by figures, was beginning to manifest itself by its influence on the number of children of school age. It looked as if the civilised part of the human race was beginning to experiment with its reproduction, just in the same way as it had already experimented with its mode of locomotion. With the fall in the birth-rate they were brought face to face with what one might call in commercial language greater appreciation of infant life, and this was the one saving feature. He thought that greater efforts should be made in future to save existing life, and to find out how many lives were lost before birth. He hoped that it would not be long before the Government brought in a Stillbirths Registration Act.

Outbreak of Diphtheria in Galashiels.

Galashiels is threatened with an outbreak of diphtheria of a somewhat severe type. Up to last Saturday there had been within the last month 16 cases, of which three had proved fatal. As the infectious disease hospital at Eastlands is already fully occupied with scarlet fever cases, these diphtheria cases have to be treated in the houses in which they occur.

The National Insurance Act in Stow, Midlothian.

At a largely attended meeting of insured persons held in Stow on Oct. 25th it was decided to call upon the authorities to establish a panel doctor in the place, as they were being entirely neglected under the Act. It will be recalled that the local medical practitioner, who is still in residence, did not see his way to go on the panel, and therefore the medical benefit has been administered from Lauder, a distance of about six miles over hill roads.

St. Andrews University Rectorial Election.

The election of a Lord Rector of St. Andrews University took place on Oct. 25th in the United College Hall. Principal Donaldson presided, and the Earl of Aberdeen was elected Rector for the ensuing three years. There was no other nomination.

Aberdeen City Insurance Panel.

The following statement has been compiled showing the distribution of insurance patients among medical men in Aberdeen:—Fewer than 50 patients, 8; 50 to 100 patients, 3; 100 to 200, 5; 200 to 300, 5; 300 to 400, 7; 400 to 500, 3; 500 to 600, 2; 600 to 700, 1; 700 to 800, 2; 800 to 900, 2; 900 to 1000, 3; 1000 to 1100, 4; 1100 to 1200, 2; 1200 to 1300, 1; 1300 to 1400, 4; 1400 to 1500, 2; 1500 to 1600, 2; 1600 to 1700, 1; 1700 to 1800, 2; 1800 to 2000, 4; 2000 to 2600, 1.

Sanatorium Benefit in Aberdeen.

During the year July, 1912, to July, 1913, the Aberdeen Insurance Committee administered sanatorium benefit to 134 males and 70 females. 73 were treated in the City Hospital, where the average stay was 90 days, and 13 were sent to Newhills, where the average duration of treatment was 84 days. Results of treatment were: fatal, 39; better, 49; worse, 1; no change, 26; outstanding, 89. Costs were: reports, £51; City Hospital, £1128 13*s.* 7*d.*; Newhills, £147 11*s.* 1*d.*; domiciliary, £38 0*s.* 0½*d.*; total, £1365 4*s.* 8½*d.* The number of insured persons treated in the Royal Infirmary from July 15th, 1912, to July 15th, 1913, were: in-patients, 31; out-patients, 28; total, 59.

Insurance Lectures in Aberdeen.

It is understood that, subject to the Scottish Insurance Commissioners sanctioning the expenditure of £100, under Section 60 of the National Insurance Act, 1911, steps will be taken to institute a series of simple lectures in different districts of Aberdeen, embracing among other subjects (1) the chief laws of health; (2) the choice of nourishing food; (3) digestion and indigestion; (4) care of insured persons

drawing sickness benefit, &c. Intimation has been received that the Commissioners are sympathetic towards the scheme.

Inclusive Fees in Medicine at Glasgow University.

In their report to be submitted at the half-yearly meeting of the general council of Glasgow University this week the business committee say they have now considered the statement prepared by the subcommittee appointed at the conference at Perth in March last of representatives of the general councils of Edinburgh and Glasgow on the question of the inclusive fee in medicine. They are of opinion that the statement tends only to strengthen the position hitherto maintained by the council that no sufficient experience of the working and effect of an inclusive fee in other faculties has yet been gained to warrant its adoption in the much more difficult case of medicine. The committee therefore recommend that the council transmit this report to the University Court, with a renewed representation in favour of delay in the institution of an inclusive fee in medicine.

Infantile Mortality in Glasgow.

During the year 1912 there were in Glasgow 2667 deaths of infants under 1 year, which is equal to a death-rate of 122 per 1000 births. That is 14 per 1000 under the rate for last year, and is only 3 above that for 1910, which was the lowest on record. The decrease in the rate is partly ascribed by the medical officer of health of the city to the low temperatures and heavy rainfall which prevailed during the summer and autumn, when diarrhœa is specially prevalent among infants. Of these deaths, 2394 were of legitimate children and 273 of illegitimate children, representing rates of 118 and 185 respectively per 1000 births of each class. In each class there is a considerable improvement when compared over a series of years, and it is a reasonable expectation that still further reduction will result from the increased facilities for supervision which the provisions of the Notification of Births Act and of the Children Act afford. In analysing the causes of death among infants the diseases contained in the group "immaturity" constitute the largest individual portion of the infant death-rate, and represent a mean rate varying between 49 and 43 per 1000 male births, and between 39 and 34 per 1000 female births. Under existing circumstances this is to be regarded as an irreducible part of the infant death-rate—irreducible at least until the causes which prejudicially affect gestation are better known. The medical officer of health holds that there is some reason for thinking that among the poorest of the population the proportion of fat and carbohydrates in their dietary is insufficient.

Tuberculosis in East Lothian.

Haddington county council, at a meeting held on Oct. 27th, dealt with the provision of sanatoriums. Ten beds have been taken in the South-East of Scotland Combination Sanatorium, while on Phantassie Hill, near Haddington, a building originally intended for a small-pox hospital has been converted into a sanatorium with 16 beds. Strong objection was taken by some members to the establishment of this extra hospital, when the council had already decided to enter the combination. The council approved of Dr. Buchanan, the medical officer of health, instituting a tuberculosis dispensary in Tranent, to be opened one day a week.

The late Dr. John Adam, of Dingwall.

The death took place on Oct. 21st at his residence in Dingwall, of Dr. John Adam, one of the most widely known practitioners in the north of Scotland, at the comparatively early age of 57 years. A son of the late Æneas Adam, of Humberstone, he graduated at Edinburgh University after a brilliant career, and afterwards took up work in Dingwall. There he soon acquired a very good and widespread practice, penetrating into a large part of the Northern Highlands. Hard and constant work told upon his health, and some time ago he went for a trip to Africa, all his expenses being defrayed by public subscription. He never regained his former health, but continued to practise in a restricted way until the day before his death. Dr. Adam held the rank of Surgeon Lieutenant-Colonel in the Seaforth and Cameron Brigade of Territorials, and for years was a member of Dingwall town council and school board. He is survived by a widow and two daughters.

Oct. 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Insurance Commissioners and Certification.

A VERY curious situation has arisen in connexion with the payment for certification in Ireland. The £50,000 granted to Ireland in lieu of medical benefits was to be devoted largely to pay the medical profession for certification, but the medical men in the south and west stoutly refused to accept the terms and to go on the panel. Meantime, another grant of £41,000 was given to Ireland, and a distinguished metropolitan medical man made every effort to have this second sum also applied to pay for certification. He has reported to the Irish Committee that, after repeated efforts with the Insurance Commissioners, he has failed, and a special meeting of the Irish Committee has been summoned for Oct. 30th, at which the action of the Commissioners will be fully discussed. The recent attempt of the Insurance Commissioners to find by an inquiry the causes of malingering, and at the same time to evolve a scheme to deal with the £41,000—additional money given by Mr. Lloyd George provided a scheme could be formulated—has not made much progress. There is—rightly or wrongly—a feeling in the medical profession that the matter was being hurried by the Insurance Commissioners, so that if there were divided views among the profession then they could formulate some method themselves. It is most unfortunate that in Ireland the medical profession and the Insurance Commissioners seem to be unable to agree as to the best way to administer the Act, which, owing to the way it was rushed through Parliament, leaves almost every point in its working to be settled.

The Winter Session in Belfast.

The winter session of the medical school began on Oct. 14th at the university and hospital, but the opening lecture at the Royal Victoria Hospital was postponed until Tuesday, Oct. 21st, when in the presence of most of his colleagues and a large collection of students Dr. J. C. Rankin, who is in charge of the electrical department of the hospital, delivered an interesting inaugural address. After welcoming the students and pointing out the great importance of clinical work, Dr. Rankin took up seriatim the questions of the history, diagnosis, prognosis, and treatment of any case as affected by the scientific developments of modern medicine, and contrasted the present views as compared with the state of affairs which prevailed before the era of bacteriology. Finally, he referred to his own specialty—"the Cinderella of medicine"—electricity. The audience—students and medical staff—accorded Dr. Rankin a very warm vote of thanks for his valuable and suggestive address.

Monaghan Sanatorium.

The Irish Local Government Board has finally approved of the conversion of the County Monaghan Fever Hospital into a sanatorium (tuberculosis) for the county and of the transfer of the County Fever Hospital to the disused fever hospital at Killnacloy. The work of renovating the two buildings is to begin at once.

The Mater Infirmorum Hospital.

On Oct. 23rd, by invitation of the authorities of management of the Mater Infirmorum Hospital, a number of medical men and others were invited to witness a demonstration of the recent very modern electric installation of X rays, Finsen light, and auto-photography which have been placed in the hospital. The demonstration of the merits of these new modern aids to diagnosis and treatment afforded by electricity was closely followed by the invited guests, who expressed their satisfaction with the admirable results. Those present were most profitably entertained.

Epidemic Disease in Belfast.

Not in the memory of the oldest medical man practising in Belfast has there ever been so much epidemic disease. Both the Municipal Fever Hospital at Purdysburn, and the Workhouse Fever Hospital are crowded. Scarlet fever has been steadily increasing each year since the autumn of 1900, until the number attacked this year has reached already an unprecedented figure. At a meeting of the Public Health Committee of Belfast, held on Oct. 20th, the number of cases of scarlet

fever reported for the week ended Oct. 18th was actually 76. At present, in the two fever hospitals there are over 350 cases. The type of the disease is severe, renal complications and general sepsis being met with, and the mortality for hospital cases—6 per cent.—is very high, and shows the severity of the epidemic. Again, typhoid fever—which for a time had almost vanished—has in Belfast reappeared. Close on 50 cases have been treated of late at Purdysburn. There have been 13 cases in Purdysburn Fever Hospital of typhus (perhaps brought from Glasgow), over 30 of diphtheria (some of a severe laryngeal type), and 3 of acute poliomyelitis. The reason for this widespread epidemic of scarlet fever is being freely discussed in the press. Some think we in Belfast, like other large English cities, are only "coming into our own" in reference to this disease, and that scarlet fever is likely to remain with us for some time. If this is so, then all the arguments which were put forward in the past by public health authorities to show that infectious diseases could be limited, if not stamped out, by notification, isolation, hospital treatment, and disinfection, are proved to be totally fallacious. So far as Belfast is concerned, our position is infinitely worse than it was before notification of scarlet fever was in vogue, and the enormous expense to the city does not seem to be bringing any results such as one should expect. If other cities have the same experience as Belfast as regards scarlet fever, it is quite time that the reason for the total failure of public health administration to cope with scarlet fever should be inquired into.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Claim for Damages involving Scientific Investigation.

THE Paris tribunal has before it a claim for damages which is to be the occasion of a scientific investigation of a curious nature. In July, 1912, a woman riding in a cab was the victim of an accident for which the driver was held culpable, and the proprietor of the cab was ordered to pay 150 francs damages for the injuries to the shoulder and the arms sustained by the woman. It so happened that at the time of the accident the woman was in the early stage of pregnancy, and on Dec. 9th of the same year she was confined of a girl who showed serious congenital deformities —viz., the entire absence of the two hands and of a part of the left forearm. The woman considered her child's deformities, in conformity with the popular belief, to be the consequence of the accident sustained by herself during pregnancy, and now sues the cab proprietor for further damages to the extent of 50,000 francs. The court has nominated three experts, Dr. Pozzi, Dr. Bonnaire, and Dr. Paul, to furnish answers to the following questions: 1. Was the arrest of development of which the child was the victim during intra-uterine life really caused by the accident in July? 2. Was this congenital infirmity the direct consequence of the traumatism suffered by the mother, or could it be connected with other anatomo-pathological causes? If the first question be answered in the affirmative the experts are to estimate the disability entailed on the child through life as a result of its infirmity. This report, entrusted as it is to highly competent specialists, will form the basis of award by the courts in similar cases that not infrequently come before them, in which up to now there has been nothing save popular tradition to guide them. This tradition, widespread though it is, at present rests on no precise scientific considerations, if we except the experiments of Dareste on the artificial creation of monstrosities in the embryo of the fowl by punctures, infection, or intoxication during incubation; but it is not known whether these conclusions are applicable to the human fœtus under such conditions as the congenital deficiencies of limbs or parts thereof.

The Publication of Memoirs of the Académie de Médecine.

Hitherto the *Bulletin des Séances de l'Académie de Médecine* has included the text of the scientific communications of its members only, or of reports by them of other communications read at its meetings. Non-members of the Academy, permitted to read communications before it, were allowed only a mention of the titles of them in the *Bulletin*. The communication itself was submitted to some member of the Academy to prepare a report thereon, and this report could be published in the *Bulletin*, but very frequently the report was not forthcoming until after a lapse of some months, and occasionally no report at all was made. Yet the regulations of the Academy forbade the publication of the author's paper *in extenso* elsewhere, even though no report was published in the *Bulletin*. These conditions resulted in the withdrawal of much interest from the publications of the Academy. Many of its members, who are for the most part advanced in years, do not make any communication at its meetings, but only read administrative reports imposed upon each in turn on various statistical matters, on the competitions for the numerous prizes awarded yearly by the Academy, on the authorisation for the exploitation of mineral waters, and so forth, all of them subjects foreign to the progress of science properly so-called. It was at the other learned societies rather than at the Académie de Médecine that the most interesting communications, even those of academicians, were brought forward. The new permanent secretary who succeeded M. Jaccoud, Professor Debove, has originated a new procedure, in which he has the unanimous support of his colleagues, which will entirely change this state of things. Henceforth authors who are not members of the Academy but are permitted by the executive to deliver a lecture at a public meeting, must hand in at the same time an abstract of their communication, not exceeding two printed pages in length, which will be published in the *Bulletin* if approved by the Bureau. This proviso is for the purpose of making it possible to eliminate articles of a quackish character that might be sprung upon the Academy by surprise. Further, the author of a communication so accepted must undertake that no part of it shall be published elsewhere until eight days after the publication of the *Bulletin*. Finally, candidates for membership, whether as honorary or active members, must have read an original communication in the year preceding the election if the vacancy to be filled is not of more than a year's standing, or two communications if it is of longer duration. It is hoped that under these conditions the *Bulletin* will acquire greater interest, and that the meetings of the Academy will be more frequented by serious workers, who for a long time have held aloof in face of the difficulties they experienced in securing publication for their works.

Professional Secrecy and Industrial Accidents.

M. Perreau, a professor in the Faculty of Law at Toulouse, has discussed in the *Presse Médicale* the difficulties arising out of the law of professional secrecy in the case of the subjects of industrial accidents. The rule in France is that the medical man summoned by the patient is bound by the most absolute tie to secrecy under all and every circumstance. In 1885 a decree of the Cour de Cassation condemned a medical man who, after the death of the painter, Bastien Lepage, wrote in the newspapers, in order to deny the false reports of suicide that the celebrated artist succumbed to cancer of the intestine. The like secrecy is imposed on all medical men, and even on the entire medical *personnel* of a hospital or clinic to which the injured person has been carried, either with his consent or even without it when in an emergency he is not in a condition to give it. The only persons released from the obligation to professional secrecy are those appointed by the courts and those sent by an insurance company to report on a case, but then only on condition that they make known their status. In practice almost inevitable violations of this secrecy occur daily, especially in hospital, where the diagnosis of the patient's disease is written on a card by his bed, and where the medical adviser, speaking before his assistants or visiting *confrères*, makes no mystery of his patient's condition. When an illustrious personage becomes ill the daily newspapers are accustomed to publish a bulletin, which also constitutes a violation of professional secrecy on the part of the physicians in charge of the case. Nevertheless the legal provisions are very strict, and should anyone complain that he has suffered damage thereby the courts are compelled to award him compensation, even if his medical man has acted in good faith and without any intention of doing harm, as in the case of Bastien Lepage. In the case of those injured by industrial accidents, when the insurance company sends its physician

to ask the medical attendant as to his diagnosis, M. Perreau advises that the latter should refuse to answer. A hospital physician is authorised to confide his diagnosis to a *confrère* only when he knows that the latter is the patient's ordinary medical attendant, and that it constitutes in fact a consultation in the latter's interest. It is even possible that an insurance physician who should obtain information by concealing his status would expose himself to a charge of abuse of confidence. As to the violation of professional secrecy in clinical lectures delivered in the wards or in the amphitheatre, when the patient is effectively designated by the number of his bed, M. Perreau thinks that this again is a violation of professional secrecy and carries a legal risk for the physician. As it is very difficult to exercise control over a mixed audience of students and medical men, it follows that it is more prudent to choose for demonstration patients other than those under the cognisance of the law in regard to industrial accidents and compulsory insurance. It would also be wise of the medical man to ascertain in his first question in regard to an injured patient brought to him, whether he has not to deal with one of that category.

Ether in Peritonitis.

The Société de Chirurgie is at present occupying itself with the question of the use of ether in peritonitis, a subject to which attention was called by the previous work of M. Savariaud and M. Morestin. On Oct. 16th M. Broca laid before the society the results of his personal experience with it. All the children suffering from diffuse peritonitis the result of acute appendicitis have borne the procedure perfectly, and M. Broca is convinced that without it many of them must certainly have succumbed. It is true, four of the children died later from intestinal obstruction due to adhesions, but it seems clear that the ether had no part in that. This treatment only arrests the progress of the peritonitis; it does not remove results already produced. M. Morestin, as the result of a wide experience, feels sure that free flushing of the peritoneal cavity with ether will assure success.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Control of Dangerous Lunatics and of the Mentally Defective.

AT the annual meeting of the Association of Government Medical Officers Dr. A. Leppmann, one of the medical men attached to the Berlin law courts, read a paper on the Protection of Society Against Dangerous Lunatics. He said that the public had an instinctive sympathy for the insane and believed all the statements which certain newspapers published to the effect that sane persons were liable to be confined in lunatic asylums. Public opinion was desirous that measures should be taken to prevent illegal proceedings in connexion with the administration of lunatic asylums, but at the same time the public required to be better protected against dangerous lunatics than has hitherto been the case. He expressed a decided opinion that this was the duty of the police, who ought to have the power to arrest dangerous lunatics and convey them immediately to asylums. The distinctive appellation "dangerous lunatic" must not be too narrowly defined. The laws concerning these matters were not very clear and some law courts have decided that the police had not the power to arrest as lunatics persons who had not been placed under guardianship by a judge. Dr. Leppmann considered that the law courts ought only to interfere with the confinement of insane persons in asylums when they have committed a crime of which they have been found not guilty because of insanity. Mentally defective persons with antisocial tendencies must be rendered harmless by confining them in asylums, especially those who were not insane in the strict sense of the law, but have committed misdemeanours. He wished, farther, that insane persons outside asylums should be registered and inspected regularly by medical officers. The laws concerning the placing of insane persons under guardianship must be reformed, so that insane persons possessing some means may be made responsible for such damage as they may have caused to others. The public ought also to be informed by articles in the newspapers, by lectures, and by other means, of the great damage done by mentally defective persons.

An Institution for the Study of Alcoholism.

A committee has been formed for the establishment of an institution for the study of alcoholism, and an appeal has been issued on behalf of the committee for the purpose of collecting the necessary funds. It is said in the appeal that similar institutions are in course of formation in Russia as well as in the United States of America, and that Germany ought not to be in the background, since about 30,000 persons die in this country annually from the effects of over-indulgence in spirituous liquors. The institution will provide facilities for studying by modern methods the action of alcohol on the organism of the human subject and the lower animals in sickness as well as in health. A hospital will be connected with the institution, and collective investigations from a statistical and medico-legal point of view are contemplated.

The Battle of the Clubs.

As already announced in these columns[1] the laws relative to workmen's insurance have been reformed. The new statutes concerned with insurance against invalidity and against accidents came into force as long ago as Jan. 1st, 1912, and Jan. 1st, 1913, respectively; their modifications compared with the earlier law are relatively slight and of little interest for the great majority of medical men, but the statutes concerned with insurance against sickness have undergone a thorough change and the new provisions are of the greatest importance for the medical profession. It need only be mentioned that the new law allows, as a rule, only one general sick club for every city or town, and that no new sick clubs besides the general sick club may be founded, although under certain conditions some of the existing trade sick clubs may continue to work provided that their financial basis is absolutely sure, and that they have a sufficient number of members. In the city of Berlin alone, of the more than 100 existing sick-clubs only 12 will be allowed in future to continue their operations in addition to the general sick club which will have about 500,000 members. Many medical men will therefore lose the practice which they have had in the clubs now to be discontinued. The law does not contain provisions concerning the system of club practice; it is entirely left to the clubs whether they will introduce the free-choice system or not. In many parts of Germany no agreement has hithero been entered into between the local medical union and the clubs. In Berlin, however, after lengthy negotiations between representatives of the clubs and the medical profession, conducted under the supervision of the director of the district insurance office, an arrangement is likely to be agreed upon—an arrangement which, although far from being satisfactory, nevertheless does away with certain objectionable features. The free-choice system without restriction could not be obtained for the big general sick club, but a committee composed of members of the committee of the clubs and of the medical men will deal with the appointment of new medical officers. Certain guarantees against an arbitrary removal from office have also been obtained and the salaries are somewhat raised. The general sick club will, moreover, admit the medical officers of the dissolved sick clubs to practice, so they will at least recover a part of their income lost from practice. Throughout most of the provinces and the empire an arrangement has failed to be agreed upon, although it was hoped until recently that a conflict might be avoided. In the last issue of the Journal of the Deutscher Aerztevereins-Bund the presidents of the Aerztevereins-Bund and of the Leipziger Verband respectively announce that the sick clubs have declined to enter into further negotiations and that a strike is imminent. Nobody knows indeed what will become of club practice after Jan. 1st if no agreement has been come to. The clubs are already preparing their "mobilisation" and are trying to obtain strike breakers by advertising in the daily newspapers that they want medical officers who will devote their whole time to club practice under the most favourable conditions at salaries of 15,000 marks (£750), and even more, per annum. Some medical men will certainly apply for these appointments, but evidently too few to suffice for the requirements of some

[1] THE LANCET, July 22nd, 1911, p. 262.

millions of insured persons. A terrible muddle seems ahead of the medical profession.

The Medical Curriculum and Lectures on Social Medicine

Some time ago the Government asked the medical faculties of the German universities whether they believed it advisable that lectures on social medicine and an examination on the subject should be made compulsory for medical students. It was further stated that the lectures and the examination would deal with such questions as the Workmen's Insurance Act, industrial diseases and their prophylaxis, the medical aspect of insurance against accidents, and the care of cripples, tuberculous patients, and infants. The majority of the faculties answered in the negative, explaining that the medical curriculum was already overcrowded with lectures and that medical students, moreover, did not yet possess the special knowledge which would enable them to derive any advantage from lectures on social medicine. The Government has therefore resolved to proceed no further with the proposal in its present form, but as an alternative to have lectures on social medicine delivered during the practical year after the State examination.

Revolver Shots in a Court of Honour.

A medical man had lately to appear before the court of honour of the medical chamber of the province of Westphalia in Münster. When the prosecutor asked that he should be adjudged guilty and proposed a fine of 300 marks (£15) the defendant declared that the court had better not fine him at all. When the court, after having deliberated *in camerâ*, returned to the court room and announced that the defendant was fined according to the proposal of the prosecutor, the defendant in a state of the greatest excitement drew a revolver from his pocket and fired several shots at the members, fortunately without hitting anyone. He was at once arrested, and it was found that he had formerly shown signs of mental aberration which had become aggravated by the excitement connected with the trial.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

An Unusual Method of Infection with Rabies.

IN a small Hungarian village, quite close to the Roumanian frontier, a boy was bitten by a stray dog. The parents reported the case to the village medical man, who sent the patient to the Pasteur Institute in Budapest, where he received inoculations for 17 days, and was then allowed to return home, being considered safe from the danger of rabies. Scarcely had he arrived home when his mother showed symptoms of rabies and was taken to a hospital, where she died in a state of terrible suffering. As she had not been bitten by the dog, which, judging from the consequences, was rabid, the question arose how she could have contracted the infection. The first idea was that she might have kissed her son before he was carried to the Pasteur Institute, but at that period of the case, only two or three days after being bitten, he could hardly be capable of producing rabies in another person. This assumption, therefore, had to be dropped, and the practitioner in attendance ultimately discovered that the woman had sewn the boy's trousers where the dog had torn them in biting him and she had wetted the thread by pulling it between her lips—the same thread which had been in contact with the trouser material. The medical man thinks that the torn part of the trousers had imbibed the saliva of the mad dog, and the thread which was pulled through this saliva had conveyed the virus to the mother's mouth when she wetted the thread with her lips.

The Declining Birth-rate in Hungary.

The last Census has shown that the birth-rate in Hungary is declining. As our sole consolation with regard to the great infant mortality was the high birth-rate, so the announcement that the latter is decreasing has come as a painful surprise. The Minister of Public Hygiene advised the formation of a committee with the view to find out the real cause of the fall of the birth-rate. This committee began its work in 1910 and finished it this year. Its report, which was addressed to the Minister of Internal Affairs, says that the true cause of the fall of the birth-rate depends on the national prosperity being less than formerly, and not on defective hygienic or sanitary conditions. Especially during the last two decades the diminution of the people's earnings has compelled thousands of women to work for their living, and many thousands of them are thereby precluded from the possibility of becoming mothers simply by reason of insufficiency of income. This fact induced the committee to take some measures in order to create easier conditions for mothers and women of child-bearing age, particularly among the working classes. This interference of the committee has been successful, inasmuch as the State sick clubs now support pregnant women and nursing mothers more liberally than is the case anywhere else on the Continent. Whilst in Germany and Austria pregnant women and nursing mothers get only monetary support for a few weeks, the Hungarian State workmen insurance system gives them not only monetary assistance but also free attendance by medical men and midwives, and free medicines and dressings. The monetary support, which if necessary can be given for 20 weeks, is payable for six weeks even if the woman is capable of earning her livelihood after two weeks. The committee, however, states that all these benefits are not sufficient to increase the birth-rate. The most important matter, in its opinion, is to ensure rest and leisure for the mother, and this must be provided for with even greater liberality. The committee, in fact, recommends the adoption of the Italian law, according to which no women must be employed in industrial work within 30 days after childbirth, and the women thus debarred from work, if they are not members of some sick club, must be supported by the State. The committee has computed that the outlay involved would come to about 700,000 kronen per annum.

Cholera in Hungary.

After an entire absence of fresh cases of cholera for three weeks new outbreaks are reported from the counties of Szilaqy and Kolozs. Great anxiety was caused by one case in Kolozsvár, the patient having collapsed in the University. In consequence of this case the University has been closed without any date being assigned for the reopening, and as most of the students come from different counties they have gone home to their parents—a circumstance which has caused a great deal of trouble, because all the towns and villages where they stopped on their way had to be medically examined and isolated for a period of eight days.

Statistics of the Medical Profession in Hungary.

The number of medical men in Hungary amounts to 5682, of whom 1472 reside in Budapest, the capital, and 4172 of the remainder practise in the country. In Croatia and Dalmatia there are 442 medical men, and in Bosnia-Herzegovina there are 253. In Budapest there are 27 public hospitals, and in the country there are 331. In Croatia and Dalmatia there are 23 hospitals, and in Bosnia-Herzegovina there are 27. The number of asylums for children is 17; there are 12 schools for midwives and 10 maternity hospitals. The number of watering-places (*kur-orten*) and thermal stations in the country is 232. Medicinal springs are also in a great abundance, their number being 79. The medical staff of the University of Budapest consists of 22 ordinary professors, 30 extraordinary professors, 101 lecturers, and 67 teachers, while in the University of Klausenburg there are 11 ordinary professors, 6 extraordinary professors, 15 lecturers, and 29 teachers.

Oct. 25th.

MEDICO-PSYCHOLOGICAL CLINIC.—The inaugural meeting of this clinic will be held in the Botanical Theatre at University College, London, on Wednesday next, Nov. 5th, at 3 o'clock. Lord Sandwich will take the chair, and the speakers will include Dr. Maurice Craig, Dr. Constance Long, Professor Spearman, and Professor McDougall.

DONATIONS AND BEQUESTS.—The Chelsea Hospital for Women has received a grant of £500 from the trustees of the Zunz Bequest. This donation is additional to the trustees' promise of £10,000 towards the rebuilding fund.—Mr. Albert Brassey, of Heythorp Park, has given £1000 towards the building fund for the Radcliffe Infirmary and County Hospital, Oxford.

Obituary.

JUST MARIE MARCELLIN LUCAS-CHAMPIONNIERE, M.D. PARIS,

FORMERLY SURGEON TO THE PARIS HOSPITALS AND PRESIDENT OF THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS.

Dr. Lucas-Championnière died suddenly on Oct. 22nd during a meeting of the committee of the Institut de France. He had finished reading to his colleagues the lecture that he was to deliver as the representative of the Académie des Sciences on the following Saturday at the annual meeting of the Institut, the subject of which was Trephining in Prehistoric Ages. He had resumed his seat and one of his colleagues had already begun to speak when Dr. Lucas-Championnière collapsed in his chair. His colleagues ran to his assistance, among them Professor Guyon, who at once performed artificial respiration, but without avail. He was already dead, from either embolism or failure of the heart, for he was affected with heart disease and some years ago suffered from an attack of angina pectoris, since which time he had exercised strict precautions. His name was one of the most renowned in French surgery—indeed, in all contemporary surgery. He was largely instrumental in introducing on the continent Listerian methods, having been one of that great man's first disciples in 1868, when as a young interne of the Paris hospitals he attended the surgical course at Glasgow, and later at Edinburgh in 1875.

Just Lucas-Championnière, M.D.

Dr. Lucas-Championnière was born on August 15th, 1843, at St. Léonard (Oise). He was the son of a distinguished physician, who in 1840 founded one of the earliest medical journals in France, the *Journal de Médecine et de Chirurgie Pratiques*. He received his academic education at the Collège Rollin and his professional education at the University of Paris, becoming interne of the hospitals in 1865, gaining the silver medal of the interneship in 1869, and in 1870 proceeding to the M.D. degree. In 1874 he was appointed surgeon to the hospitals, but he failed at the *concours d'agrégation* of the Faculty of Medicine to qualify for the professoriate—a misfortune in which he has had Claude Bernard and many other *savants* for his companions. His first service was that of surgeon-in-chief of the maternity of the Hôpital Cochin. He then directed in succession the surgical services of the Hôpital Tenon, the Hôpital St. Louis, the Hôpital Beaujon, and finally the Hôtel-Dieu. He retired in 1906. Numerous as were his activities, his chief claim to distinction will rest on his having been the earliest and most active advocate of the antiseptic method. He devoted to it between 1875 and 1880 numerous publications, and in later days he still wrote frequently to contend against the exaggerated ideas of contemporary antisepsis consequent on pushing the doctrine to extremes, and to discuss the value of asepsis, which he regarded as a disguised antisepsis. His book, entitled "Pratique de la Chirurgie Antiseptique," was reviewed in THE LANCET of Oct. 23rd, 1909. Between 1880 and 1893 he wrote much on the radical cure of hernia, on trephining in relation to cerebral localisation, and more recently on the treatment of fractures by massage and early mobilisation, on which subject he delivered an address at the annual meeting of the Cardiff Medical Association on June 4th, 1909, which was published and commented on in our columns of June 12th of that year. He was an earnest advocate of the bicycle, the merits of which for sufferers from hernia and varicosities he constantly extolled. His last clinical essay was a paper on the treatment of club foot by resection of the calcaneum, read before the International Medical Congress in London last August.

Dr. Lucas-Championnière was elected a member of the Académie de Médecine in 1894. He was president of the Société d'Obstétrique et de Gynécologie, of the Société de Chirurgie, of the Société de Médecine Publique, the Société d'Enseignement Médical des Hôpitaux de Paris, which he founded in 1907, the Syndicat de la Presse Médicale Française, and of the International Association of the Medical Press. In the last-named capacity he presided on August 5th in London over the Fifth Congress of the Medical Press. Finally, he was nominated only in February last a member of the Académie des Sciences. He was also an honorary member of many foreign societies and academies, including the honorary Fellowship of the Royal College of Surgeons of England (1906). He was also a Commander of the Legion of Honour. His energy was great. He travelled much and attended many international congresses, and visited England, where he had many friends, nearly every year. He was the spokesman of the deputation of distinguished French surgeons which on August 11th placed a wreath of red roses tied with tricolour ribbon before the bust of Lister in the Royal College of Surgeons; and to him was committed at the closing session of the International Medical Congress the honourable duty of speaking on behalf of France.

To many British and American medical men Dr. Lucas-Championnière was personally known, as he was a regular attendant of international congresses, an extremely kind and genial host in Paris, and spoke English with considerable fluency. His genial and cultured personality will long remain a memory with his numerous friends and aquaintances on this side of the Channel, who are now sympathising with his widow and children in their great loss.

ARTHUR BRISTOWE CARPENTER, M.A., M.B. OXON.

Croydon and a large circle of friends have recently suffered a great loss by the death of Dr. Arthur Bristowe Carpenter, of Wykeham House, Bedford Park, Croydon. He was a son of Dr. Alfred Carpenter, a well-known Croydon practitioner, and received his early education at Brighton, later winning scholarships at Winchester and New College, Oxford. In 1876 he entered as a student at St. Thomas's Hospital, where he held the post of house surgeon and house physician, having graduated in medicine at his university.

For some time Dr. Carpenter was chairman of the medical committee of the Croydon General Hospital, and filled the position with conspicuous ability. His kindliness, keen sense of fairness, natural courtesy, and geniality will long be remembered with affectionate regard by his colleagues, and some of those who knew him intimately for many years will recall him as the ablest chairman that ever presided over the medical committee. Up to within a few days of his death he continued to attend to his duties as senior medical officer to the Hospital although suffering great pain, which he bore with remarkable stoicism. By scarcely any one was the extent of

his sufferings known, or even suspected; but it was patent to all, even to the most unwilling eyes, that he was afflicted with a disease which must soon prove fatal.

In the religious and scientific life of Croydon he had taken an active part and endeared himself to a circle quite outside that of his profession. His funeral took place from St. James's Church, at which he had acted as churchwarden for many years. The interment was at Bandon Hill Cemetery, Wallington, and was attended by a large number of the principal inhabitants of the borough and by the leading members of the medical profession residing in the district. Dr. Carpenter had been a composer of repute and master of the Surrey Bell-ringers' Association, and a muffled peal was therefore rung over his grave. During the service also a muffled peal was rung on the bells of the old parish church and again in the evening for an hour and a half, and similar peals were rung at St. Peter's and Beddington Church.

Dr. Carpenter leaves a widow and five daughters.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Schuhl, lecturer on midwifery in the Nancy Faculty of Medicine.—Dr. Reginald H. Fitz, formerly professor of medicine in Harvard University, Boston.—Dr. Nathan Jacobson, professor of clinical surgery in Syracuse University Medical College.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis: Institution of Popular Lectures and Museum.

THE General Direction of the Sanitary Services of the Ottoman Empire has published a communication to the effect that the sanitary authorities of the city, alarmed at the great ravages tuberculosis is making in Constantinople, are taking the necessary measures to combat the disease. The Government's activity alone, however, is not sufficient to stem the evil. The coöperation of the population is indispensable. It is necessary that the public should understand better the nature of the disease, the steps to be adopted against it, and the conditions under which favourable treatment can be undertaken. The General Sanitary Direction, assisted by the authorities of the Gullhaneh Hospital, have instituted gratuitous lectures in the conference hall of the hospital with some such idea as this in view. These lectures will begin on Monday, Oct. 27th, the day when this letter will probably reach you, and will last for several weeks from 12 to 2 o'clock for women and from 2 to 4 for men. Dr. Reshad Riza Bey will hold an introductory conference for women on the day of opening, which conference will be repeated next day for men. Two medical men of the Gullhaneh Hospital will be present on each occasion and furnish every information. In connexion with the lectures a tuberculosis museum is being established in Stambul, where printed instructions are to be distributed to the public having reference, not only to tuberculosis, but to other infectious diseases, notably cholera.

The Illness of Enver Bey.

Colonel Enver Bey, one of the protagonists of the Ottoman Revolution, is lying seriously ill with appendicitis. I called on him at his house in Beshiktash, but I could not see him. His father, however, readily received me, and supplied me with the following details. Enver Bey has suffered from appendicitis for quite a long time. On several occasions he has had very severe attacks and has been advised to submit to surgical operation. Being constantly engaged in active military service he could not follow the advice. When in Adrianople, however, the attacks caused him such excruciating pains that he had at once to be transported to the capital for surgical treatment. The Sultan, who is his father-in-law, sent his chief physician, Dr. Hairi Bey, who together with Dr. Djemil Pasha, a well-known operator among the Moslems, performed the necessary operation. This, it appears now, did not prove successful, while the patient considerably neglected instructions. A second operation was decided upon, and after this the condition of the patient was more satisfactory, although further surgical interference may be required. The medical attendants of Enver Bey are very hopeful of a successful issue, as the patient is young and possesses a robust constitution.

"Audi alteram partem."

THE EXAMINATION IN ANATOMY FOR THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—I trust that Professor Elliot Smith and your readers will not imagine that there is any change of policy at the Royal College of Surgeons because at present only one of the four members of the Board of Examiners in Anatomy for the Fellowship is a professed anatomist. There is no such change of policy. Difficulties often arise in making a selection from the candidates who apply. For example, a desirable candidate may be for the moment ineligible because the school to which he is attached is already represented. During the last 15 years there have always been two, and at one time there were three, professed anatomists on the board, which, it will be remembered, changes pretty frequently. This does not suggest that the Council are unsympathetic with the enlightened views of modern anatomists, or are endeavouring to hinder their efforts.

I cordially endorse Professor Elliot Smith's remarks about the Museum, the lectures, and the demonstrations, the value of which is undoubted and the attendance disappointing.

I am, Sir, yours faithfully,

Wimpole-street, W., Oct. 25th, 1913. RICKMAN J. GODLEE.

To the Editor of THE LANCET.

SIR,—The science of anatomy, with its professors, labours under the disability of having no special academic degree indicating the position of those who teach it. Having regard to the supreme importance of the two basal sciences, anatomy and physiology, in the study of medicine, it is somewhat surprising that the enterprise of the universities in this country has not led to the establishment of a special degree, in anatomy on the one hand and physiology on the other, more especially in these days, when the demand for academic distinction is being so universally recognised. A mere qualifying double diploma for a medical man is now at a discount; it implies, with truth, a legal competency of medical knowledge, but it does not carry with it the weight of any special distinction. Oxford University has set the example of creating a special distinction for ophthalmologists, known as the "D.O." of Oxford. The advantage of this is the assurance that the holder has "done" something in ophthalmology. In future years, perhaps, this distinction or a similar one, may become necessary to anyone applying for an ophthalmic appointment. The principle here exemplified applies equally to the sciences of anatomy and physiology. It is scarcely to the point for the anatomists to quarrel with the Council of the Royal College of Surgeons for ignoring the claims of the professed anatomists for appointments as examiners at the College. What have the anatomists done to place themselves upon an academic footing, to attain a position as experts, to secure, apart from their professorships, an exclusive academic title indicating the science they profess? It remains a fact, in these advanced days, that the two greatest sciences of medicine, the sciences which bulk most largely in medical knowledge, are entirely without academic recognition, and yet this labelling process must be expedient. It standardises the expert knowledge, it provides an incentive for special work, it establishes an exclusiveness for those who seek to profit by their strenuous labour.

Meanwhile the Council of the Royal College of Surgeons

might timely consider the question of applying for power to create a special diploma in anatomy by virtue of the College being "the custodian of the greatest anatomical museum in existence."

I am, Sir, yours faithfully,

Wimpole-street, W., Oct. 25th, 1913. PERCY DUNN.

To the Editor of THE LANCET.

SIR,—Sir William Osler's address will attract the attention of all thinking men who wish to see British surgery maintain and improve its position in the world. The good and temperate letter of the President of the Royal College of Surgeons of England in your issue of Oct. 18th indicates certain possible fallacies in the suggestion to award the Fellowship wholly or partly as a result of research work in surgery. But he also asks us to remember that the Fellowship is not a necessity. Now is this actually the fact? I venture to think that for certain men the Fellowship is a necessity—viz., for the man who wishes to get on the surgical staff of any large hospital. Certainly I was so informed before I took up the study of medicine, and as I had determined ultimately to practise surgery I made a dead set for the Fellowship.

I hope I may be excused, under the veil of anonymity, if I write here entirely about myself. I believe my personal experiences are those of many, and that their exposure may help to the comprehension of a very important discussion. Up to the time of passing a qualifying examination in anatomy and physiology I had received, and no doubt there are many others similarly situated, a liberal and sound scientific training at a large public school (where I was a scholar), at my university (of my college in which I was also a scholar), and at my hospital. I can recall no reason to suppose that my intellect, such as it was, was failing, and I had the great advantage on my side of good heredity for the purpose of scientific surgical work—a point referred to by Sir William Osler. At this stage the system which should have helped me on did me a bad turn in the following manner. I worked solidly at anatomy and physiology for 15 months, entered for the Primary, and failed. I had one other serious attempt, and failed again and more decidedly, perhaps being stale at the time. I decided that it was impossible for an average man, anxious to go in for surgical work, to play a declared game, for he could not make sure of passing an examination conducted in such a manner. Obviously in any *viva-voce* examination the chance of the candidate going from bad to worse is greater than that of his going from good to better, and the race against time in the papers is not conducive to setting out the subjects clearly. There is no schedule of the subjects, both of which are vast. I doubt if anyone could know the whole perfectly. My course in physiology had been a logical sequence until I attended some classes for the Primary Fellowship, when I was crammed with theory stated as fact, much of it wrong and all of it illogically compounded. This I was able to neglect, but I found I was supposed to memorise large quantities of technicalities having little or no value as a mental training, such as laboratory methods, numbers, spectra, compositions of foods, &c., the underlying principles counting *nil*. I was not examined logically in practical physiology, which was one of the subjects I had given most attention to in the laboratory for some years, but I was asked questions on bread and potatoes. I understand that such a procedure has largely passed out of the examination, but the unfairness used to be great. and those who had been coached in the bread-and-butter business passed, though they might know nothing of practical experimental physiology. These observations determined me to treat the examination as a 5-guinea lottery, with a 2 to 1 chance against drawing a winning number, and to waste no more time and to ruin no more of such brain as was left me by working for it. In due course I drew a winning number.

For the Final I proceeded in the same way. I had one serious attempt after holding a house surgeoncy and doing nine months' steady grind at surgery only, but six rather high fences brought down the poor steeplechaser, and so I referred this part of the examination, like the first, to ordeal by lot. In one such attempt, going in for the examination quite unprepared, I found I could not go wrong, and I believe I passed easily. I have seldom been more annoyed. In return for all my time and work for the Primary Fellowship I had acquired nothing of use to me that I did not possess at the time of passing the qualifying examination in anatomy and physiology. I had a worse knowledge of physiology and perhaps a better knowledge of anatomy; but at what a cost! And all those years I might have been learning my future profession. True, the work for the Final Fellowship has its value, much of it will be of use ultimately, although here the artificial nature of the operative surgery part of the examination made the preparation for the test rather a waste in my time.

The net result to me of my work to obtain the Fellowship was that by screwing time out of the system to do my own work in my own way I obtained a fair knowledge of surgery. But in other ways I was hopelessly out of the running with my fellow students and had spent certain money in fees. If during the process my resources had failed I should have been debarred from what I hope will prove to be my life's work—work that I had determined on at the age of 16 and now enjoy. My opportunity for this work I owe to the Fellowship, but partly to good luck. Properly speaking, I should owe it to ability.

In THE LANCET for Dec. 12th, 1908, pp. 1773–4, there is a letter suggesting a system of apprenticeship to a hospital (not to an individual), with two-thirds of the marks for the apprenticeship and one-third for the examination. Sir William Osler would add marks for research. Let the "examination idea" be to help the candidate, not to keep him back, and leave the ultimate result as regards practice to the man and the public, and I do not think much harm will come of it and the right men will be chosen.

A good type of man is generally chosen for the Fellowship by the examination, but often several such are refused, while some of the chosen are hopelessly unpractical. Some of those refused have originality, and the late Sir Henry T. Butlin was often heard to say, "We want at this time originators in surgery." The system keeps back such persons unduly, and tends to make men cynical instead of enthusiastic. I am often asked about the Fellowship examinations, and I unhesitatingly advise everyone to go in, whether he knows his work or not. I say: "You can do yourself no harm beyond the loss of a few pounds; you may do yourself much good; you cannot make a certainty of passing by hard work, even if you keep your health, and often after hard work you make a worse show than by going in fresh and unsophisticated."

I am, Sir, yours faithfully,

Oct. 18th, 1913. F.R.C.S. ENG.

EXAMINATIONS, EXAMINERS, AND EXAMINEES.

To the Editor of THE LANCET.

SIR,—Sir Rickman Godlee's letter criticising a small point in Sir William Osler's address on the above subject illustrates the hard task that is before those who would endeavour to save our educational system from the curse of the examination incubus. Sir William Osler, by his powerful indictment of the present position of the examination in medical education, reminds us that he belongs to the rapidly increasing body of educationists who recognise the futility of the examination as an instrument of education and calls on his fellow teachers of medicine to revolt against its domination and overthrow it. To illustrate a point in his argument he cites the pass list of the examination for the Fellowship of the Royal College of Surgeons of England. At once the President of the College defends the examination—not as an instrument of education but as a method of selection. He does not answer the criticism that the preparation for the examination prevents and interrupts the education that might make a man a good surgeon, but states that without the examination the College might not make an absolutely fair selection as between those who did and those who did not know some detail of anatomy. Reformers of education must recognise that there are numbers of people, some interested and some not in the least interested in education, who cling to the examination as the only safe and fair method of selection. A good many teachers of medicine have a greater belief in the value of the examination as a means of distinguishing between the relative merits of their pupils than in its evil effect in preventing large numbers of them from having any merits

worth speaking of. To meet this point Sir William Osler suggests an alternative method of selection at least for Fellows of the College, but Sir Rickman Godlee will have none of it. Fortunately the belief in examination even as a method of selection is not at present universal, and presidents of colleges are successfully chosen by other methods. One day perhaps some other fair method of selecting candidates even for the Civil Service may be devised, and the path made easier for those who would remove the destructive influence of the examination from educational courses. Meanwhile Sir William Osler introduces to his fellow teachers a proposal of the greatest value for lessening the harm which is undoubtedly being done by the increasing number, stringency, and externality (if I may coin a word) of medical examinations. He suggests the introduction into the examination of records of practical work actually carried out by the candidate in the wards, laboratories, and post-mortem rooms of his school.

One of my objects in taking part in this correspondence is to urge upon my junior fellow teachers in medical schools the advisability of preparing for such an arrangement, even before it is adopted as a requirement by examining boards. The records of a man's practical work in nearly all departments of medical education might be, and ought to be, much more fully kept than is at present the case. The card system of recording a student's progress at his school, which I suppose is in operation in most places, should be much extended. Full reports of the impressions produced by his work upon his several teachers, together with examples or duplicates of actual work done should be preserved and made available for ready reference. The compilation of a semi-public dossier of this sort would favourably affect the student's attitude towards all his practical work. The inspection by a university authority of a school thus equipped would be a proceeding of some real worth, and the necessary material would be available when in due course examining bodies realised that what a man had done was of more value as an indication of his capacity than what he knew.

I am, Sir, yours faithfully.

London, W., Oct. 28th, 1913. LAURISTON E. SHAW.

To the Editor of THE LANCET.

SIR,—Sir William Osler in his recent address upon this subject has stigmatised a recent primary examination for the Fellowship of the Royal College of Surgeons as "the high water mark of examination futility," and Sir Rickman J. Godlee himself admitted in his letter upon the same subject that he would not say "that the condition of things is quite satisfactory."

As far as the anatomical portion of this examination is concerned, there seems to be an increased danger of this unsatisfactory state of things becoming more acute. The Primary Fellowship is generally recognised as being a high test of anatomical knowledge, and quite recently the regulations have been altered so as to permit the candidate displaying more fully his advanced knowledge in the written part of the examination. As things now stand students are specially selected and specially trained in advanced anatomy, and they have excellent facilities afforded by a choice of questions for writing answers which embody the results of prolonged work in the advanced branches of their subject.

It may have occurred to some that with two of the examiners being surgeons in the active practice of their profession, a possible embarrassment might have been felt by these busy practical men in weighing correctly the answers in subjects which do not come within their practical range. A busy London surgeon cannot be expected to be a specialist in, say, embryology or in the considerations of pure morphology. But at any rate two professed anatomists were associated with them in the work of examining, and the teachers of students found some assurance in this. But as the examining body is at present constituted, only one pure anatomist sits in judgment on the candidates; and three surgeons are examining instead of two. Such a condition of affairs is thoroughly unfair, first, to the highly trained students; and second, to the professed anatomists who teach them. It is quite impossible for an active surgeon to keep himself abreast of the modern developments of a highly specialised study such as human anatomy now is.

It may be said that the examination is not intended to be one in advanced anatomy, but in the anatomy that concerns the surgeon. But the reply is easy that the final examination in surgical anatomy still awaits the candidate; and that the questions set in recent papers clearly show that embryology and higher anatomy are essential subjects in the examination. The development of the diaphragm was recently asked in a paper. What busy surgeon in London practice would claim to be a critic of recent views or even to be conversant with the literature of the past ten years on such a subject? And yet they are solemnly weighing the answers submitted by highly trained students on such matters. The physiologists have thrown off the yoke: and the candidates in physiology are examined by men who have at any rate claims to be considered as physiologists, and it is absurd that candidates and teachers should submit to surgeons being the judges of knowledge in a subject which has long since outgrown their grasp.

At almost every school in London candidates are taught by professed anatomists, and it is a gross injustice to these teachers that their students are examined by men whose specialised knowledge is not equal to the task.

I am, Sir, yours faithfully,

Oct. 20th, 1913. A LONDON TEACHER OF ANATOMY.

THE SPENS (STOKES-ADAMS) SYNDROME.

To the Editor of THE LANCET.

SIR,—It has been claimed that the first case of heart-block was described by Robert Adams, of Dublin, in the year 1827. From this fact, together with the later but more detailed account of further cases by Stokes, also of Dublin, in the year 1842, the syndrome to which the condition may give rise has been termed the Stokes-Adams syndrome. The claim for the double name is thus based upon those of its asserted first describers. I have lately come across a complete and carefully described case of this character published in the year 1792—that is, 35 years before Adams, and 50 years before Stokes. If, as I hope to show, this case is an undoubted instance of the syndrome, then it is right to claim that the syndrome should be renamed after the earliest discoverer. The account of the case is to be found in a book of some 592 pages, entitled "Medical Commentaries for the Year M.D.CCXCII." Succeeding the title it states, "Exhibiting a concise view of the latest and most important discoveries in medicine and medical philosophy, collected and published by Andrew Duncan, M.D., F.R. & A.SS. Ed." The book was published in Edinburgh in the year 1793. The case is to be found commencing p. 458, and is entitled, "History of a Case in which there took place a remarkable Slowness of the Pulse. Communicated to Dr. Duncan by Dr. Thomas Spens, Physician in Edinburgh." It begins:—

> On the 16th of May, 1792, about 9 o'clock in the evening, I was sent for to see T. R., a man in the 54th year of his age, a common labouring mechanic. ..... I was much surprised, upon examining the state of his pulse, to find that it beat only twenty-four strokes to the minute. These strokes, however, as far as I could judge, were at perfectly equal intervals, and of the natural strength of the pulse of a man in good health. He informed me, that, about 3 o'clock in the afternoon, he had been suddenly taken ill while standing in the street; that he had fallen to the ground senseless; and that, according to the accounts given him, by those who were present, he had continued in that state for about five minutes. ..... From the time of this first attack, till I saw him, he had been affected with three other fits, mainly of a similar nature. These, however, were attended with some convulsive motions of his limbs, and with screaming during the fit, ... nor had he, at that time, any other complaint. ..... Upon visiting him, on the morning of the 17th, I found that he had been attacked with several fits during the night, ... Upon examining his pulse I found that it beat only twenty-three strokes in the minute ..... an hour after, I found it in precisely the same state as before. He was now directed to take some spirit of hartshorn; but, by mistake, it was given him very little diluted, and produced much uneasiness in his throat and mouth. From this cause I found him in great distress at 1 o'clock; but it seemed to have produced no change in

the state of his pulse, which at this time beat twenty-four strokes in a minute and was of the same strength and regularity as before ..... In the morning of the 18th I was informed that ..... he had been frequently faint ..... his pulse beat only twenty-six strokes in the minute. About 8 in the evening he had no sooner smelt it (newly toasted bread) than he felt some of the sensations of a beginning fit; and, as soon as he had tasted it he almost instantly cried out, and fell back senseless, with smart convulsions of all his muscles. He apparently recovered in a few seconds; but hardly any pulse could be felt for a good many seconds. On the morning of the 19th I learnt that ..... he had been attacked with frequent fits, attended with violent convulsions ..... at three in the afternoon, I found that it (the pulse) beat only 10 strokes a minute, though it still continued equally strong and regular as before ..... he expired on the 20th. The day after his death, the body was opened by Mr. Fyfe, and, upon the most careful examination, no morbid appearance of any consequence could be discovered either in the thorax or abdomen.

All the features of the case point to its being an undoubted example of heart-block. The slow, regular pulse, the occasional faints, losses of consciousness, and convulsions, during which, if prolonged, hardly any pulse could be felt, are typical. Especially to be noted is the unaffected state of the pulse even following the distress of the too strong hartshorn, this static character of the pulse under varying circumstances being a striking feature of heart-block. Dr. Spens finally has evidence that two years previously the pulse of the patient presented no abnormality.

It appears, then, that this case and not Dr. Adams's must assert priority, and if priority of discovery is to be the claim for naming this syndrome then the Stokes-Adams syndrome must in future be known as the Spens syndrome.

I had a personal conversation with a distinguished consulting physician of Edinburgh on Oct. 24th, to whom I related the facts, when he told me that Dr. Spens was a well-known physician in his day. His portrait, by Raeburn, hangs now in the Royal Archers' Hall of Edinburgh, and a copy of this picture, which is claimed to be one of Raeburn's best, also hangs in the hall of the Royal College of Physicians in Edinburgh. Dr. Thomas Spens was famous, not only as a physician, but as an archer.

I am, Sir, yours faithfully,

C. EDGAR LEA, M.D., M.R.C.P. Lond.,
Medical Registrar, Manchester Royal Infirmary; Hon. Assistant Physician, Salford Royal Hospital.

Oct. 25th, 1913.

WORKMEN AND HERNIA.

To the Editor of THE LANCET.

SIR,—In the course of a year I see a great many cases of rupture. I see them principally in two capacities, one as examiner to an insurance company which does a lot of work in connexion with the Workmen's Compensation and Employers' Liability Acts, the other as honorary surgeon to the Hospital Saturday Fund.

I have noticed lately that in practically every case of hernia which I examine for insurance purposes the patient announces that he is waiting to be sent for to go into hospital for operation. The waiting list at the hospital is usually a long one, so this entails an average waiting period of from four to six weeks. The rupture is held by the workman to be the result of an accident which occurred in the course of his employment, and as a rule it is impossible to prove otherwise. As medical men we know that these cases are mainly of two kinds—viz., either congenital or acquired; in the former the first descent of gut into the patent canal may be the result of a strain at work, in the latter the real condition is a weakness of the lower abdominal muscles, and the immediate cause, or last straw, causing actual rupture to take place is some such strain as coughing, straining at stool, vomiting, or some special strain at work. Nowadays any natural strain causing rupture in workmen is practically unheard of, some special strain arising out of employment being usually the alleged cause.

In my hospital days it was taught that operation was not advisable in the acquired ruptures of men of and past middle age, the reason being that they were so likely to recur. The modern practice seems to be to operate on almost any case of hernia. Judging by the frequency with which I see men at the Hospital Saturday Fund coming up for trusses after having unsuccessful operations for hernia, I am driven to doubt the wisdom of the modern tendency, and I think it would be well if surgeons made full inquiry into the ultimate results of their operation cases before continuing their present practice. There are many men with acquired hernia, doing heavy work and wearing trusses, and if they are careful to wear an efficient truss from the start they seem to have little inconvenience. In practically every case one sees of acquired hernia after alleged accident, one is able to say that with a suitable truss the patient could return to work at once. As the result of the present tendency for operation, one is met with the answer that the patient is waiting to be sent for by the hospital for operation, and it is easy to advance incontrovertible reasons why he should not work meanwhile; it is not safe to work without a truss, and the wearing of a truss is liable at first to cause chafing which would prejudice the chances of a successful operation. The result is that the workman with a rupture is well aware that he is in a position to take a prolonged holiday at the expense of his employers and his club, the first part being the period of waiting for a bed, the second the stay in hospital, and the third the three months, or often indefinitely more, which he can wait before admitting his ability to undertake light work. The net result of this is a vast increase of the number of persons under the demoralising influences of prolonged compensation and idleness, and a corresponding increase in the number of previously good workmen spoiled in the process. When one sees the frequency of failures in the results of operation for the "radical cure" of acquired hernia, one inclines to think that it would be well if surgeons looked into the position before continuing to operate on all cases alike, and ask themselves, in view of the results, is it worth while to continue to fill their beds with these cases, and are they not doing more harm than good by enabling these workmen to continue to draw compensation for indefinite periods? Of course, I do not intend these remarks to apply to the younger case of congenital hernia, in which obviously the chance of success is good.

A further result of my experience is that I should advise all employers of labour to insist on a medical examination before taking on new employees; many do not do this, much labour is casual, and most employers insure. At a glance a medical examiner would detect either a rupture which might be "fathered" on to some future accident, or the weakness of the lower abdominal muscles and consequent bulging, which Sir Frederick Treves in his surgical lectures at the London Hospital used to describe as "hernial belly," a condition in which it is only a question of when, not whether, a rupture will appear in a man who has to undergo much strain, either from cough or heavy lifting. The neglect of this precaution is one of the great contributory causes of the frequent increases of premium that companies are bound to make in order to carry on their business at all; one could easily name half a dozen others. Sir John Collie has demonstrated in the case of certain corporations which do their own insurance that this preliminary medical examination is of value.

I know of a case, an extreme one, in which a small, undersized, and under-developed individual, aged 40, was taken on to do navvying work. In June, 1910, he got ruptured when using a pick. He was operated on at St. Bartholomew's Hospital in September of that year. After the operation he would not do any work. In October, 1911, he was taken to the county court. The medical assessor held that the abdominal muscle weakness, which I considered to be the predisposing cause which had led up to the rupture, was due to the lying up, operation, &c., and found that he was not fit for work. His rupture was at any rate temporarily cured, and with a truss he could have done some work. I examined him again in April, 1913. Up to this period he had drawn compensation and was not working. I thought there was some slight improvement in his abdominal condition (showing that to some extent the assessor may have been right), and gave my opinion that with a truss (double) he ought to go to work. I have not heard any more of him yet; perhaps his case has been settled by the payment of a

lump sum. Had this man been examined before being taken on as a navvy no one would have passed him for such work on account of his deficient physique, and abdominal wall weakness would almost certainly have been noted. In my opinion he should never have been operated on.

I venture to publish this note, hoping it may cause perhaps some surgeons to give consideration to certain elements in these cases, which in the ordinary way do not come within their ken. It is necessarily based on impressions and not on statistics. My Hospital Saturday Fund work introduces me to the failures and not to the successes, and possibly causes me to take an unduly pessimistic view of the value of operation for the cure of acquired hernia. At any rate, it will not be wasted if it stimulates any surgeon to make particular inquiry as to how his cases are after an interval of, say, five years after operation.

I am, Sir, yours faithfully,

A. P. GIBBONS, M.B. Lond.

Finsbury-circus, E.C., Oct. 22nd, 1913.

To the Editor of THE LANCET.

SIR,—Perhaps some of your correspondents would give me their views upon the following question: What period should elapse between the radical operation for inguinal hernia and the resumption of full work—heavy industrial—colliers, steelworkers, &c.—work? I am in the habit of allowing in cases which have had a normal post-operative course after 17 to 21 days in hospital—two weeks in bed—resumption of full work in ten weeks after operation, and after any suppuration—superficial or fascial—a period of 12 to 14 weeks. I do not advise trusses, and I have not had more than some 5 per cent. of recurrences in cases in which one cannot always pick and choose.

I do not think that the periods allowed are too long or that they should be shortened, but there is always pressure on the part of the employers, through medical men, for a much earlier resumption.

I am, Sir, yours faithfully,

Oct. 24th, 1913. M.A., M.D., F.R.C.S.

CLAIMS AND CONSULTATIONS.

To the Editor of THE LANCET.

SIR,—In the letters last week from Mr. Albert Benthall and from Mr. J. J. Scanlan, I think the ideas of Mr. Benthall in advocating the formation of a small medical board with full powers as to being able to give "final and conclusive decisions" an impossible proposition, as all evidences in the Law Courts go to prove that in contested cases the medical experts are often absolutely at variance.

In Mr. Scanlan's letter, I quite agree that something is wanted to put the safety of the medical fees on the same par as the legal fees. But I would draw his attention to the fact that his well-known position and standing as an expert on "claims" matters give him a position not enjoyed by the ordinary medical practitioner who has to take his fee in the usual medical account, whereas Mr. Scanlan stands in the position of the consultant who obtains his fee usually at the time of consultation, or it is guaranteed to him by the practitioner in charge of the case.

I am, Sir, yours faithfully,

J. M. CLARKE, M.B., B.Ch., M.R.C.S.

Regent-street, W., Oct. 20th, 1913.

To the Editor of THE LANCET.

SIR,—Although I am not a member of the medical profession, may I crave your indulgence to permit me to reply to Mr. J. J. Scanlan's letter in this week's issue of THE LANCET?

Having informed us that the "first steps taken by insurance companies upon receiving a claim by an injured party are to have him medically examined," Mr. Scanlan complains that they are asked to pay for the man's own doctor's attendance at such examination. Mr. Scanlan evades any discussion as to the legality of the demand, so we have only to consider the equitable right.

What is the position? The injured man has a medical attendant and is quite satisfied with his advice and treatment, and accordingly enters his claim. His opponents (the insurance company) have to prepare a defence, and with the view of strengthening this they adopt the method of having the injured man medically examined; therefore it is quite clear that this is in their own interest only. That being so, why should the man be mulcted in that expenditure?

It is argued that the companies sometimes find that there are very trivial injuries to be seen. Well, if it be true, the companies have learnt that much. Is that any reason why the man should be asked to pay? Insurance companies employ inspectors to investigate claims made on them, and must often find that they are not liable for many such claims; would it be held that as they have obtained that information the claimant should be called upon to pay the cost of the inquiries? It must be agreed that the item is only one of many which fall on the debit side of the "profit and loss" account of the companies' books.

I must not encroach too extensively on your space, although there are many arguments one could submit against Mr. Scanlan's letter.

I am, Sir, yours faithfully,

Gray's Inn-place, W.C., Oct. 27th, 1913. M. WILSON.

ACCIDENTS DUE TO SALVARSAN.

To the Editor of THE LANCET.

SIR,—Since the introduction of salvarsan three and a half years have passed. In the meantime a large number of deaths (about 200) and of cases of blindness, deafness, encephalitis hæmorrhagica, paralysis, epileptiform convulsions, and grave poisoning after the employment of salvarsan have been recorded in medical literature. As, in club and private practice, either through fear of publicity or because many colleagues by reason of principle do not publicly record cases, or upon other grounds, many deaths and accidents are not published, I therefore beg my colleagues to inform me of all cases of death, blindness, convulsions, paralysis, &c., and generally all grave and dangerous incidents occurring after the use of salvarsan, and to add a brief history of the illness, in order that collective statistics may be compiled. For facilitating the sifting of the material received the name of the respective practitioner and place of residence should be given. It is absolutely necessary to collect the concealed cases in order to add them to those cases already reported in literature, and thus be able to form an opinion as to the harmfulness or harmlessness of salvarsan.

I am, Sir, yours faithfully,

Dr. Med. DREUW.

Potsdamerstrasse 31A, Berlin, Oct. 21st, 1913.

UNIVERSITY OF OXFORD: PHILIP WALKER STUDENTSHIP IN PATHOLOGY.—The professor of pathology gives notice that an election to this studentship will take place in January, 1914. The studentship was founded for the furtherance of original research in pathology. It is of the annual value of £200, and is tenable for three years. The student may be of either sex and need not necessarily be a member of the University of Oxford, nor be legally qualified to practise the profession of medicine. While holding the office the time of the student must be wholly devoted to original pathological research; no business or profession may be followed which in the opinion of the professor of pathology and of the board of managers would interfere with the pursuit of original inquiries. The place and the nature of the studies of the student are subject to the approval of the professor of pathology, but the student is bound to pursue these studies within the University during at least three terms of his tenure of his studentship. This requirement may, however, in special circumstances be dispensed with. If the work done by the student be of exceptional promise the studentship may be extended for a second period not exceeding two years. Intending candidates are requested to send letters of application, with three testimonials (one of which should vouch for the candidate's personal character and general education), to the Registrar of the University, University Registry, Oxford, so as to reach him on or before Jan. 7th, 1914; ten copies of these papers must be submitted. Copies of the full regulations may be obtained from this source.—The following degrees have been conferred:—D.M., A. D. Waterhouse and G. D. H. Carpenter; B.M., B.Ch., G. W. Carte.

THE NATIONAL INSURANCE ACT.

THE NECESSITY OF SELECTING A MEDICAL ADVISER ON THE PANEL.

A notice has been issued by the National Health Insurance Commission (England) to insured persons entitled to medical benefit—Form $\frac{99}{I.C.}$, pointing out to those who have not yet selected a medical adviser the necessity of doing so without delay. The lists of available practitioners and approved institutions for 1914 can be consulted at the nearest post-office, while the clerks to the Insurance Committees will give any required information. The notice does not apply to Manchester and Salford.

APPROVED SOCIETIES AND SUBSCRIPTIONS TO HOSPITALS.

The difficulty of getting into working order the machinery for carrying out the Insurance Act is exemplified by the fact that only during the past ten days have the Commissioners issued a circular explaining the powers of Approved Societies to subscribe to hospitals, dispensaries, or district nursing associations under Section 21, while further regulations to provide that such expenditure shall be reckoned as expenditure upon sickness benefit are promised but not yet made. The circular states that hospital subscriptions must come from the societies' ordinary benefit funds, and that it is for them to decide whether such expenditure may be expected to promote recovery and so economise expenditure on sickness benefit. Such relief to the sickness benefit fund could not be immediate, so that societies, before incurring expenditure under Section 21, should, the circular suggests, consider their immediate liabilities for sickness benefit and obtain actuarial advice. In the first instance, the Commissioners suggest, it may not be advisable to incur the expenditure unless savings sufficient to cover it have been realised. Societies are informed that they are entitled to place at the disposal of members or wives of members the services of certified midwives, who should be paid out of the sum payable as maternity benefit to such individuals.

LONDON INSURANCE COMMITTEE.

At the meeting of the London Insurance Committee on Oct. 23rd the date for the revision of the medical list was fixed for Jan. 8th, 1914. It was hoped to fix the last day of the year as being a date likely to be easily remembered by all concerned, but the Insurance Commissioners intimated that they would not be ready until Nov. 8th to issue the Amendment Regulations, of which two months' notice must be given. Some discussion took place on a proposal to extend the services of the newly appointed medical referees to Approved Societies in respect of cases in which incapacity might come within the scope of the Workmen's Compensation Acts and cases where disease was thought to be due to misconduct. Several speakers urged that the referees would be no more competent to decide these questions than the general practitioner, but ultimately the Committee decided to ask the Insurance Commissioners to approve the extension.

The following particulars were given as to the work of the medical referees to date: Applications for referees' services received, 389; reports furnished to Approved Societies, 221. Of the first 255 cases 108 had been declared capable of work, 86 had been declared incapable, and 61 declared off of their own accord. Therefore, 34 per cent. of the cases remained on the insurance fund.

Mr. ALBAN GORDON moved for a return of the number of cases in which medical treatment had not been provided on the ground that it was beyond the scope of a medical practitioner of ordinary competence and skill. The proposal found no seconder, but the Chairman remarked that there had been very few such cases, and they had all been dealt with as far as could be ascertained.

Dr. H. H. MILLS moved—

That it be referred to the Medical Benefit Subcommittee to consider and report as to the facilities for obtaining clinical investigation and treatment for insured persons at the metropolitan hospitals.

He urged the importance of coördination of the insurance service with the work done in the hospitals, and was confident that the inquiries of the Insurance Committee would be received in a cordial spirit.

The motion was carried unanimously.

The Committee dealt with one complaint (found to be proved) by a doctor against an insured person and with a number of complaints against doctors. In one case the allegations were found to have been substantiated; in four cases the Committee considered that the complaints were not substantiated. In another case a transfer was effected, in another no action was taken, and in a third the practitioner was asked to refund the money expended by the insured person in obtaining treatment elsewhere. There were five complaints of neglect (accompanied in some instances, it was alleged, by the use of abusive language) against one practitioner. The Committee found that in two cases the use of strong language was proved, but that in the only cases of neglect substantiated a deputy was at fault. It was explained that for this reason the removal of the doctor from the panel was not recommended, although he was warned that an obligation rested upon him to provide a proper substitute when absent.

A return was presented showing that on July 14th, 1913, the number of insured persons in the County of London was 1,505,519, of whom 73,819 were deposit contributors. It was added that since that date the number had remained practically stationary.

ACCUMULATED FUNDS IN HERTFORDSHIRE.

In reply to a letter asking for suggestions as to the distribution of funds accumulated through insured persons having failed to select their medical attendants the Hertfordshire Medical Committee has made the following proposal:—

That the Hertfordshire Medical Committee, after consultation with the practitioners upon the panel, is prepared collectively to accept for treatment all insured persons who may require the same, including transfers, the holders of travellers' vouchers, insured persons moving temporarily from one address to another within the county, and insured persons accorded domiciliary treatment as part of their sanatorium benefit, if the County Insurance Committee is prepared to make a numerical distribution of the residue of insured persons, quarter by quarter, among the doctors upon the panel upon whom rests the collective responsibility for the treatment of such residue and of making payments to practitioners out of the panel fund in accordance with such numerical distribution.

This raises the important preliminary question whether a "numerical distribution of the residue of insured persons" can be made under the Act or the Regulations hitherto framed by the Commissioners, the answer to which must apparently be in the negative; and also whether the Insurance Commissioners can, if they should desire to do so, make or sanction any regulation which does not involve the distribution by name of individual patients to individual medical men, the answer to which is, at least, doubtful.

THE INSURANCE ACT IN THE HIGHLANDS.

At Kinloch Rannoch in Perthshire the following situation has arisen. The district extends from Tummelbridge to the head of Loch Rannoch, a distance of about 25 miles, and until the passing of the Insurance Act a medical practitioner discharged the duties of medical officer to the district, having a guarantee from the proprietors of the annual sum of £55 10*s*. This, however, was withdrawn on the Act being passed, and the operation of the Act made such a reduction in the income of the gentleman referred to that he was unable to continue his attendance in the district. This has left Kinloch Rannoch without any resident medical practitioner and with none nearer to it, or to parts of it, than a distance of 17 miles. It is stated that the parish council of the district has taken the matter in hand and has been enabled, with the assistance of the proprietors, to offer an income of £198 10*s*. to secure the presence of a medical practitioner in a district which contains about 300 persons insured under the Act.

ROYAL DENTAL HOSPITAL.—On Wednesday evening, Nov. 19th, at 8.15 P.M., the Strolling Players will give a performance of Mr. Somerset Maugham's play, *The Tenth Man*, at the Royal Court Theatre, Sloane-square, S.W., in aid of this hospital. Tickets may be obtained from the secretary of the Royal Dental Hospital, 32, Leicester-square London, W.C.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in October the following candidates passed in the subjects indicated:—

Surgery.—W. Alcock (Section II.), Sheffield; A. C. O. Brown (Section II.), Birmingham; W. S. Hyde (Section I.), Guy's Hospital; W. E. Masters (Section II.), L. C. Smith (Sections I. and II.), and W. V. Tothill (Sections I. and II.), London Hospital; and C. G. Waddington (Section II.), Leeds.

Medicine.—C. Duncan (Section II.), W. H. Lister (Section I.), and S. E. Murray (Section II.), Durham; C. G. Waddington (Sections I. and II.), Leeds; and A. H. Willson (Sections I. and II.), London Hospital.

Forensic Medicine.—A. C. O. Brown, Birmingham; and D. Schonken and J. D. Schonken, Amsterdam.

Midwifery.—A. C. O. Brown, Birmingham; G. B. Holroyd and W. V. Tothill, London Hospital; and A. K. C. Wyborn, Middlesex Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: W. Alcock, C. Duncan, S. E. Murray, W. E. Masters, and W. V. Tothill.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Wilhelm Ceelen has been recognised as *privat-docent* of General and Pathological Anatomy, and Dr. Max Stickel as *privat-docent* of Midwifery and Gynæcology.—*Chicago (University of Illinois):* Dr. Albert C. Eycleshymer, professor in St. Louis University, has been appointed to the chair of anatomy.—*Florence:* Dr. Gerolamo Gatti, extraordinary professor of external pathology, has been promoted to Ordinary Professor.—*Genoa:* Dr. David Vallebona, of Rome, has been recognised as *privat-docent* of Physical Therapeutics.—*Göttingen:* Dr. Wilhelm Lange, of Greifswald, has been appointed Extraordinary Professor of Otology and Laryngology in succession to the late Dr. Bürkner.—*Innsbruck:* Dr. Steyner, of Greifswald, has been offered the chair of Medicine in succession to Dr. Schmidt, who is going to Prague, and Dr. Windaus, of Freiburg, has been offered the chair of Medical Chemistry in succession to Dr. Pregl.—*Kiel:* Dr. F. Kehrer has been recognised as *privat-docent* of Neurology and Psychology.—*Lausanne:* Dr. L. Michaud, physician in the Medical Clinic of the University of Kiel, has been offered the chair of Clinical Medicine.—*Mobile (University of Alabama):* Dr. Howard H. Bell has been appointed Professor of Pathological Anatomy and of Bacteriology.—*Naples:* Dr. Edmondo Berger has been recognised as *privat-docent* of Medicine; and Dr. Antonio Simoni as *privat-docent* of Operative Medicine.—*Prague (German University):* Dr. R. Schmidt, of Innsbruck, has been appointed to the chair of Medicine in succession to the late Dr. Przibram.—*Rome:* Dr. Giovanni B. Tramontini has been recognised as *privat-docent* of Internal Pathology; Dr. Giovanni Francechini as *privat-docent* of Syphiligraphy; Dr. Fredrico Zuccari as *privat-docent* of Traumatology; and Dr. Adolfo Montuori, of Naples, as *privat-docent* of Experimental Physiology—*Salamanca:* Dr. E. Nogueras, professor in Santiago (Spain), has been appointed to the chair of Pædiatry.—*Sienna:* Dr. Ugo Noferi has been recognised as *privat-docent* of Operative Medicine.—*Turin:* Dr. Roberto Massalongo has been recognised as *privat-docent* of Neurology; and Dr. Ignazio Dionisio as *privat-docent* of Otology.—*Vienna:* Dr. A. Herz and Dr. E. Zác have been appointed as *privat-docenten* of Medicine; Dr. G. A. Wagner as *privat-docent* of Midwifery and Gynæcology; and Dr. H. Königstein as *privat-docent* of Dermatology and Syphiligraphy.

NATIONAL DENTAL HOSPITAL.—The students' annual dinner will be held on Friday, Nov. 21st, at the Trocadéro Restaurant, Piccadilly-circus, at 6.30 for 7 o'clock, under the chairmanship of Professor Arthur Underwood.

LONDON LOCK HOSPITAL AND RESCUE HOME.—A festival dinner in support of this institution will be held on Tuesday, Nov. 4th, at the Whitehall Rooms, Hôtel Métropole, London, at 7.15 for 7.30 o'clock. The chair will be taken by the Duke of Devonshire.

FOREIGN STUDENTS IN GERMAN UNIVERSITIES.—A good deal of inconvenience is being experienced not only in Munich but in many other German universities by the increasing influx of foreign—especially of Russian—students. The Prussian Universities having made more stringent regulations about the numbers admissible, these students are driven to enrol themselves in Bavarian, Saxon, and other non-Prussian faculties.

THE Marquess of Linlithgow will preside over the Congress of the Royal Institute of Public Health to be held in Edinburgh from Wednesday, July 8th, to Monday, July 13th, 1914, inclusive.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ARMSTRONG, JANET, M.B., Ch.B. Edin., has been appointed Clinical Assistant at the Royal Free Hospital.
BLAIR, MARY A., M.D., B.S. Lond., has been appointed Clinical Assistant in the Gynæcological Department at the Royal Free Hospital.
BOUSFIELD, FLORENCE H., M.B., B.S. Lond., has been appointed House Surgeon at the Royal Free Hospital.
BROWN, R. DODS, M.D., Ch.B. Edin., F.R.C.P. Edin., has been appointed Physician-Superintendent at James Murray's Royal Asylum, Perth.
CLARKE, H., M.B., B.S., has been appointed Junior Obstetric Assistant at the Royal Free Hospital.
DEARNLEY, GERTRUDE, M.B., B.S. Lond., has been appointed House Physician at the Royal Free Hospital.
DORRELL, E. ARTHUR, F.R.C.S. Eng., has been appointed Assistant Ophthalmic Surgeon to the Prince of Wales's General Hospital, Tottenham, N.
HUNTER, JAMES, M.B., Ch.B. Aberd., has been appointed Medical Officer and Public Vaccinator for the Parish of Forgue, Aberdeenshire.
LEACH, R. E. H., M.B., B.S. Oxon., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Bungay District of the county of Suffolk.
MITCHELL, H. V., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Clacton-on-Sea District of the county of Essex.
PICKARD, ELLEN M., M.D. Lond., has been appointed Medical Registrar at the Royal Free Hospital.
RICHARDSON, CATHERINE MARY, M.D. Edin., D.P.H., has been appointed Assistant School Medical Officer at Stockton-on-Tees.
TAYLOR, R. BREWITT, M.B., B.S. Lond., has been appointed House Physician at the Royal Free Hospital.
THOMSON, J. C., M.D. Edin., D.P.H., D.T.M. & H. Camb., has been appointed Senior Assistant County Medical Officer, primarily for the duties of Tuberculosis Officer, County of Dumfries.
WRIGLEY, F. G., M.D. Vict., has been appointed Honorary Assistant Surgeon to the Manchester Ear Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARGYLE AND BUTE ASYLUM, Lochgilphead.—Assistant Medical Officer, unmarried. Salary £200 per annum, with apartments, board, and laundry.
BATH, ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer. Salary £120 per annum, with lodging, board, and washing.
BIRMINGHAM CITY FEVER HOSPITAL, Little Bromwich.—Assistant Medical Officer. Salary £150 per annum, with board and residence.
BIRMINGHAM, QUEEN'S HOSPITAL.—Radiographer. Salary £100 per annum.
BIRMINGHAM, ROMSLEY HILL SANATORIUM FOR CONSUMPTIVES.—Resident Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and laundry.
BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Pathologist. Salary £50 per annum.
BRADFORD POOR-LAW UNION HOSPITAL AND WORKHOUSE.—Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with rations, apartments, and laundry.
BRADFORD UNION, EASTBY SANATORIUM.—Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with rations, apartments, and laundry.
BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Two Resident Medical Officers, unmarried. Salaries £160 per annum, with rooms, coals, gas, and attendance.
BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £80 per annum, with apartments, board, and laundry.
BRISTOL ROYAL INFIRMARY.—House Surgeon for six months for Throat, Nose, and Ear. Salary £75 per annum, with board, apartments, and laundry. Also Dental House Surgeon for six months. Salary at rate of £100 per annum, with board, apartments, and laundry. Also Honorary Assistant Physician.
BROMSGROVE, WORCESTERSHIRE COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £225 per annum, with quarters, board, washing, and attendance.
BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary £120 per annum, with rooms and board.

NORTHAMPTON COUNTY ASYLUM, Berry Wood, Northampton.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.
NORTHAMPTON GENERAL HOSPITAL.—Senior Resident Medical Officer, unmarried. Salary £120 per annum, with apartments, board, washing, attendance, &c.
NORTHAMPTONSHIRE COUNTY COUNCIL EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £250 per annum.

NORWICH, JENNY LIND INFIRMARY FOR CHILDREN.—Resident Medical Officer (female) for six months. Salary £50 per annum, with board, apartments, and laundry.
NORWICH, NORFOLK AND NORWICH HOSPITAL.—Resident Surgical Officer, unmarried. Salary £100 per annum.
NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100 per annum, with board, residence, and laundry.
OXFORD COUNTY ASYLUM, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing.
PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician for six months. Salary £90 per annum, with board, residence, and washing. Also House Surgeon. Salary £100 per annum, with board, residence, and washing.
PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Assistant Gynæcologist.
READING COUNTY BOROUGH.—Tuberculosis Officer. Salary £500 per annum.
RICHMOND, SURREY, ROYAL HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board, apartments, and washing.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Assistant Physician.
ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Junior Resident Medical Officer for seven months. Salary at rate of £70 per annum, with residence, board, and laundry.
ST. MARY'S HOSPITAL, Paddington, W.—Casualty Physician. Salary £75 per annum.
SALFORD ROYAL HOSPITAL.—Honorary Gynæcologist.
SCALEBOR PARK ASYLUM, Burley-in-Wharfedale.—Assistant Medical Officer. Salary £200 per annum, with board, apartments, attendance, &c.
SCARBOROUGH HOSPITAL AND DISPENSARY.—Senior House Surgeon. Salary £100 per annum, with board, residence, &c.
SHEFFIELD ROYAL INFIRMARY.—House Surgeon for six months. Salary £80 per annum, with board and residence.
UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.—Surgical Registrar. Also Resident Medical Officer.
UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Demonstrator in the Department of Bacteriology. Salary £150 per annum.
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Surgeon to In-patients and Surgeon to Out-patients.
VIRGINIA WATER, SURREY, HOLLOWAY SANATORIUM HOSPITAL FOR THE INSANE.—Junior Assistant Medical Officer. Salary £250 per annum, with board, lodging, laundry, and attendance.
WEST HAM UNION SICK HOME, Forest-lane, Forest Gate.—Second Assistant Resident Medical Officer. Salary £120 per annum.
WEST LONDON HOSPITAL, W.—Assistant Dental Surgeon. Also Second X Ray Officer.
WESTMINSTER GENERAL DISPENSARY, 9, Gerrard-street, Soho, W.—Resident Medical Officer. Salary £120 per annum, with rooms, gas, coals, and attendance.
WORKSOP, VICTORIA HOSPITAL AND DISPENSARY.—Medical Officer and House Surgeon. Salary £150 per annum, with rooms, coal, light, and attendance.
YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £140 per annum, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Acts at Sedgeley, in the county of Stafford; at Peterborough, in the county of Northampton; at Abersychan, in the county of Monmouth; at Whaley Bridge, in the county of Chester; and at Tarbert and at Lochgilphead, in the county of Argyll.

Births, Marriages, and Deaths.

BIRTHS.

BARKLEY.—On Oct. 28th, at The Coppice, New Barnet, to Dr. William and Mrs. (*née* van Oppen) Barkley, Elsenham-street, Southfields, S.W., a daughter.
MURRAY.—On Oct. 25th, at Moncrieffe-road, Sheffield, the wife of C. Graham Murray, M.D., of a daughter.
ROOKE.—On Oct. 26th, at "Fairfield," North Finchley, N., the wife of William Stanley Rooke, M.R.C.S., L.R.C.P., of a daughter.
SIMMONS.—On Oct. 28th, at Southwick-place, Hyde Park, the wife of Dr. G. Alan Simmons, of a son.

MARRIAGES.

LACEY—BARBER.—On Oct. 23rd, at St. Andrew's, Hertford, Herts, William Stocks Lacey, L.R.C.P. Lond., M.R.C.S. Eng., L.D.S. Eng., D.M.D. Harvard, to Mabel, only daughter of Mr. and Mrs. Thomas Barber, of Castle-street, Hertford.
PADDON—GILCHRIST.—On Oct. 1st, at Indian Harbour, Labrador, Henry L. Paddon, M.R.C.S., to Mina, daughter of the late Angus Gilchrist, of Fredericktown, New Brunswick.

DEATHS.

GODSON.—On Oct. 26th, at Cheadle House, Cheadle, Cheshire, Alfred Godson, M.B., J.P., aged 77 years.
KNAGGS.—On Oct. 13th, at 7, Keynsham Parade, Cheltenham, Lieutenant-Colonel Henry Knaggs, late Army Medical Department, aged 78 years.
PARSONS.—On Oct. 29th, at Oakhyrst, 4, Park Hill-rise, Croydon, Henry Franklin Parsons, M.D., F.G.S., late of the Medical Department, Local Government Board, aged 67 years. Funeral on Saturday, Nov. 1st, at 1.40, at the Church of St. Michael and All Angels, West Croydon, and afterwards at Queen's-road Cemetery.
PARSONS.—On Oct. 25th, at Fulham Infirmary, Hammersmith, W., Amy Elizabeth, the dearly loved wife of Christopher Thackray Parsons, M.D., and second daughter of the late James Hunter, Liverpool.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

FOGS AND FANCIES.

A LONDON correspondent writes:—Fogs are much maligned phenomena. From the hygienic point of view a fog is not nearly so bad a thing as it is painted. There is a superficial distastefulness about fogs which leads them into easy disrepute. We look into their ugly faces and dislike them. The same thing happens with some persons about whom we are afterwards moved to a change of opinion. So is it with the fog. Really get to know him and you will find him a better fellow than ever you guessed. But you must treat him aright, and first of all you must make him welcome. Do not, indeed, admit him to the intimacy of your home, if you can help it, but go out bravely and mingle with him. Walk with him and run with him, and if after you have climbed the hill he ceases to be with you stifle your regrets, for you will not have to wait long at this time of the year before he is with you again when you set out. When you return from your foggy walk remember the clinging nature of your acquaintance and do not be content with washing the exposed parts of your person. If the fog has dirtied your face and neck and hands, remember that he has found out the crevices too. So wash out your eyes with boracic lotion, gargle well the inside of your mouth with some pleasant, mild antiseptic, and squirt the nostrils with the same. When you have taken these easy steps and changed your moistened clothes you will agree that a walk in the fog does as much good as a walk without it. We would not keep even children indoors on account of a fog, not, that is to say, if they are healthy and free from colds or any chest affections. If they are destined to live in a land, still more in a town, of fogs, let them quickly acquire the contempt which accompanies familiarity. Nor will they need any compulsion. The mystery, the unsuspected apparitions, and secret noises of fogs in town appeal vividly to the child's imagination, and the semi-darkness suggests to him all kinds of games which are only poor fun in the broad daylight. There are, it is true, fogs and fogs, and some people, while tolerating what they call a clean fog, find the "pea-soup" variety insufferable. On the other hand, as is well known, some asthmatic subjects are more comfortable in this atmosphere than in any other. Yellow or white, however thick or thin, clogging or cool fogs, are not the natural enemies to healthy men and women that popular opinion holds them to be.

THE CASE OF MR. H. T. HAMILTON.

To the Editor of THE LANCET.

SIR,—The following is a list of donations received this week:—

	£	s.	d.		£	s.	d.
Mrs. Staples	3	3	0	Mrs. Forcett	5	5	0
Professor E. W. White ...	2	2	0	Dr. Bishop	1	1	0
Mrs. Forsyth	0	10	0	Mr. P. Cooke	2	2	0
Mr. G. Newall	2	2	0				

I am, Sir, yours faithfully,
W. H. GIMBLETT, M.D.

86, Sutherland-avenue, Maida Vale, W., Oct. 29th, 1913.

AN "OPEN ROAST" GAS COOKING STOVE.

THERE has recently been demonstrated at the offices of the Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, London, W.C., a method of cooking by gas which in the case of joints amounts to open roasting, as opposed to the oven method or baking. The advantages of open roasting which connotes cooking by radiant heat are generally admitted. This subject was fully discussed in an annotation in THE LANCET of Feb. 28th, 1903, entitled "The Oven and the Screen." Mr. William A. Lawton, barrister-at-law, in the demonstration referred to employs in his stove simply a row of small Bunsen burners, the flames from which impinge upon an asbestos screen leaning at an angle of about 25° from the vertical in the direction of the joint to be roasted. The result is a flow of radiant heat which serves the purpose of an open fire in roasting meat. But there is a cooking heat developed also in other directions. Thus on the other side of the asbestos screen sufficient heat goes forward to prepare, amongst other things, stews, a soup, or to bake pies, while at the top a boiling saucepan can be kept going for cooking vegetables, and so forth. There is nothing closed to view in this cooker, everything is open and exposed, the principle of the close oven being entirely banished. The construction is very simple; it is a structure of stout wire, that is all, with a slanting board of asbestos in the middle giving direct radiant heat on one side and an oven heat on the other, while heat escaping at the top is utilised for cooking by boiling methods. The apparatus packs up in a small space, and consumes a very small quantity of gas, having regard to its capacity for cooking food in so many ways at the same time. Further, it can be placed on an ordinary table and requires no special fitting up, a flexible

tube is all that is necessary. It is so self-contained that it produces very little general heating effect upon the room, and cooking can be done with the stove placed close to the open window. It is one of those simple devices which so often call forth the remark, "Why wasn't it done before?" and many ugly and insanitary appliances would never have seen the light if it had been.

EUGENICS—WHAT IT IS AND WHAT IT IS NOT.

THE Eugenics Record Office at Cold Spring Harbour, Long Island, New York, and its objects were described in our United States correspondence in THE LANCET of April 19th (p. 1134). The valuable work accomplished by it in its 27 months of existence was made the subject of a report by the superintendent, Mr. H. H. Laughlin, published last June. We also reviewed at considerable length on May 17th a selected list from the publications of the office and expressed our admiration for its work. We will therefore merely quote from the report the following clear statement of the aims of eugenics, which are so commonly misapprehended—viz., that it is "not a scheme for the immediate regeneration of mankind; that it is only one of the sciences devoted to the promotion of human welfare; that it must be as slow in its practical application as it is fundamental in its scope; that it is concerned with the human make-up and its heritable units; that it attempts to classify the human stock as to its social fitness; that it is concerned with the consequences of migration; that the forces that govern sex selection and differential survival are of vital importance to it, and that its end is to devise means for cutting off the supply of defective and low grade human strains, and increase fecundity and fit matings among the innately better classes. ..... Eugenics does not seek to undo or to modify one's traits—that is a task for education to attempt—but it does seek to prevent in the future eugenically unfit matings. It is not—as one paper recently called it—'the latest social upheaver.' It does not propose to undermine the existing social and moral order, nor to destroy love, but its programme does call for the eugenical education of the intelligent classes, and for the intelligent management of defectives."

A VALUABLE CATALOGUE.

MODERN laboratory workers owe much of their success in carrying out technical operations to the admirably designed apparatus now placed at their disposal by the scientific instrument maker. In the early days of research the investigator had frequently enough not only to design but to construct the particular form of apparatus that was adapted to carrying out his own experiments. Nowadays much of this is done for him, and by inspecting the modern catalogue the chemist or physicist will get often a valuable hint from its illustrations and text as to the design and methods which will meet his own particular requirements. Apparatus are not only illustrated and described in detail, but there is commonly given also a clear description of the process for the carrying out of which the apparatus was designed. In this way the modern catalogue often becomes a valuable source of reference on analytical technique, and this is decidedly the case with a catalogue of scientific apparatus recently issued by Messrs. Baird and Tatlock, of 14, Cross-street, Hatton Garden, London, E.C., which is as complete as anything we have seen. It is an extensive volume of 1283 pages cut up into various sections which are readily found by headings which project from the pages. Each section is led off by a blue page with printing matter in relief white. These sections include general chemical apparatus, balances and weights, microscopes and microtomes, blood testing apparatus and centrifuges, bacteriological apparatus, laboratory fittings, milk-testing apparatus, gas analysis apparatus, botanical models and specimens, anatomical models, reagents, meteorological apparatus, and so forth. Lastly, one section gives a list of the principal authoritative books which have been issued dealing with the various departments of analytical practice and scientific research which find illustration in the profuse drawings of the apparatus given in the catalogue. The work must have entailed considerable labour and expense, but we are sure it will meet with a wide appreciation on the part of scientific workers.

HEALTH CONDITIONS IN THE FALKLAND ISLANDS.

THE total population of these islands (according to the 1912 Blue-book of the colony) was ascertained to be 3275, as compared with 1553 in 1881. The increase is largely due to the whaling industry, which employs 1149 males out of a total of 2370, and accounts for the small population of females, who numbered only 905. This industry also explains the presence of 1093 foreigners, mostly natives of Sweden and Norway. The birth-rate in 1912 was 16·07 per 1000, the death-rate 11·52. The following remarks are quoted from the report of Mr. H. M. Stanley Turner, Assistant Colonial Surgeon, West Falkland:—

"*Meteorological.*—It would be unwise at present to make an *ex cathedrâ* statement respecting the precise nature of the influence exerted by the meteorological conditions. Systematic observations were only commenced in 1912, and several years' accumulated data are required before the influences drawn therefrom can be of value. The following factors are, however, readily observed: (1) Marked fall of the barometer appears to be closely followed by a rise in illness; (2) the barometer maintained the highest mean level during the second and third quarters of the year, and during these quarters the sickness incidence was practically *nil*; and (3) barometric oscillation was followed by a greater rise in sickness in the two summer than in the two winter quarters.

"*Nosological returns.*—Certain features are worthy of notice—viz. (1) Entire absence of all forms of tuberculosis, malignant disease (cancer), rheumatic fever and its sequelæ, and infectious disease; and (2) the prevalence of disorders of the digestive apparatus. The freedom from serious disease has been frequently mentioned in previous reports, and though the same is true of 1912, there has been a larger number of cases under treatment, among which accidents have occupied a prominent place. Affections of the digestive system, always well to the fore, reach a total of 67, of which number the dental apparatus is responsible for no fewer than 50. These figures by no means represent the total number of sufferers, and I venture the suggestion, unsupported by statistics, that few communities probably exhibit more widespread oral sepsis. In West Falkland joint changes are seen with considerable frequency in comparatively young subjects, nearly every case being associated with oral sepsis. The joints principally affected are those of the fingers. Boils (furunculosis) still exist in West Falkland, though on the whole they are less prevalent. Many of these cases recover without calling in medical help."

A "TABLOID" TUBERCULIN DILUTION OUTFIT.

Messrs. Burroughs Wellcome and Co., Snow Hill Buildings, London, E.C., have devised an outfit for the purpose of making in a few minutes and under thoroughly satisfactory conditions any required dilution of tuberculin. The equipment consists of a neat aluminised metal case measuring 8⅜ by 2½ by 5½ inches. Within is a polished metal rack fitted with holes capable of supporting in an upright position 16 bottles. The rack contains six bottles, fitted with india-rubber stoppers, each marked with a single graduation of 10 c.c. Another smaller bottle occupies a receptacle on the extreme left, and is intended for the reception of the primary dilution. By means of a stout ring affixed to the centre the rack can be pulled out for sterilising. The outfit also includes an accurately graduated pipette, a packet of "Tabloid" Absorbent Cotton, a 4-oz. bottle for saline solution, a small quantity of "Soloid" Hexamethylenetetramine, for burning, and a ½-oz. stoppered bottle for antiseptic, and so forth. The method of making the dilutions for use is as follows:—Saline solution is drawn up into the pipette to the graduation of 1 c.c. Nine-tenths are transferred to the small bottle. One-tenth is rejected and replaced by an equivalent quantity (0·1 c.c.) of undiluted tuberculin, thus forming the primary or 1 in 10 dilution which goes into the small bottle. From this any number of weaker dilutions upon a decimal scale can be prepared. The second bottle is graduated to 10 c.c. and if 9 c.c. of saline solution are placed in it and the first solution added, a 1 in 100 dilution will result. One-tenth of this may then be transferred to the third bottle to make the 1 in 1000 strength, and so on. The empty holes at the back of the rack are convenient for the reception of the bottles containing dilutions not actually in use. Each bottle is provided with a sanded surface upon which the strength of its contents should be noted.

REPORT ON THE SEYCHELLES FOR 1912.

THE Blue-book of this colony for 1912, just issued as a Parliamentary paper, shows that the population on Dec. 31st, 1912, was 23,507—about 150 to the square mile of territory. The birth-rate for the year was 30·88 per 1000 and the death-rate 14·76 per 1000. There was no outbreak of infectious or contagious disease during the year, the health of the population being good. Beri-beri, which formerly caused considerable trouble among the labourers in the outlying islands, has practically disappeared. Vaccination is carefully carried out. At the Leper Asylum nine cases were under treatment, and there was one death. The nastin treatment has been continued, but such good results have not been obtained as in the previous year, with the exception of one young patient whose improvement has been marked. The Maternity Home has been a very great success; 156 patients were admitted during the year and 135 babies born. The institution appears to be thoroughly appreciated by people of all classes. Two pupils trained in the home have obtained certificates as midwives, and are now doing good work in out-districts. The rainfall for the year reached 105·10 inches, a greater quantity than has fallen for several years. The mean temperature was 77·70°, the range being from 72·1° on Sept. 10th to 87·9° on April 7th.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The following journals, magazines, &c., have been received:—Canadian Medical Association Journal, Journal d'Urologie, Revue d'Hygiène, Interstate Medical Journal, Nordiskt Medicinskt Arkiv, Archives of Internal Medicine, Medical Review of Reviews, Post-Graduate Journal of Nervous and Mental Disease, Cleveland Medical Journal, Pacific Medical Journal, South African Medical Record, Archives Générales de Chirurgie, Biochemical Journal, Journal of Hygiene, Schmidt's Jahrbücher der In und Ausländischen Gesamten Medizin.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Mr. A. D. Hall, Mr. W. E. Brenchley, and Mr. L. M. Underwood: The Soil Solution and the Mineral Constituents of the Soil.—Prof. E. W. MacBride: Studies in Heredity—II., Further Experiments in Crossing British Species of Sea Urchins.—Prof. B. Moore and Mr. T. A. Webster: Synthesis by Sunlight in Relationship to the Origin of Life. Synthesis of Formaldehyde from Carbon Dioxide and Water by Inorganic Colloids acting as Transformers of Light Energy.—Dr. B. Blacklock and Dr. W. Yorke: The Trypanosomes causing Dourine (Mal de Coit or Beschälseuche) (communicated by Sir Ronald Ross).—Mr. T. G. Brown: On Postural and Non-postural Activities of the Mid Brain (communicated by Prof. C. S. Sherrington).—Mr. J. O. W. Barratt: The Nature of the Coagulant of the Venom of Echis Carinatus (communicated by Prof. J. N. Langley).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SUB-SECTION OF ORTHOPÆDICS (Hon. Secretaries—A. S. Blundell Bankart, E. Rock Carling): at 5 P.M.

Mr. Paul B. Roth: (1) Relaxation of the Sacro-iliac Synchondrosis; (2) Report on a Small Epidemic of Poliomyelitis.

SECTION OF PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart, C. Price-Jones), at the Imperial Cancer Research Laboratory, Queen-square, W.C.: at 8.30 P.M.

Demonstrations:

Transplantable Adenocarcinoma of Rat's Kidney.
Transplantable Fibro sarcoma of Cavy.
Spirochæte Infection of a Transplantable Sarcoma of the Mouse.
Passive Immunity to Transplanted Cancer.
Further Observations on Sarcoma Development in Transplanted Carcinomata.
Experimental Transmission of Disseminated Sclerosis to Rabbits.
Growth of Transplantable Mouse Tumours in Developing Hen Eggs.
Transplantable Sarcoma of Rat's Uterus.
And other Demonstrations.

WEDNESDAY.

SECTION OF OPHTHALMOLOGY (Hon. Secretaries—J. Herbert Parsons, Leslie Paton): at 8 P.M.

Cases:

Mr. Sydney Stephenson: Brawny Scleritis at an Early Stage.
Mr. George Coats: Small Superficial White Rings on Cornea.
Mr. J. L. Birley: Case of Pseudo-Papillitis.
Mr. Charles Killick: Complete Persistent Hyaloid Artery.
Mr. A. S. Cobbledick: (1) Ectasia of Cornea Four Years after Perforating Wound; (2) Rupture of Choroid in Myope following Labour.

Papers (at 8.30 P.M.):

Mr. George Coats: Some Instances of Disease in the Animal Eye.
Mr. C. Wray: Obstruction of Lacrymal Duct and its Treatment.

THURSDAY.

SECTION OF OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—T. Watts Eden, C. Hubert Roberts): at 8 P.M.

Discussion:

On the Relation of the Internal Secretions to the Female Characteristics and Functions in Health and Disease (opened by Dr. W. Blair Bell, followed by Miss Louise McIlroy).

The following will take part in the discussion: Dr. Archibald Garrod, F.R.S., Dr. T. R. Elliott, F.R.S., Dr. H. H. Dale, Dr. Leonard Guthrie, Mr. James Berry, and others.

Those who wish to take part in the discussion are requested to send their names to the Hon. Secretaries.

A copy of the opening paper will be sent on application.

FRIDAY.

SECTION OF LARYNGOLOGY (Hon. Secretaries—E. A. Peters, Cecil I. Graham): at 4 P.M.

Cases and Specimens:

Will be shown by Mr. Herbert Tilley, Dr. Watson Williams, Dr. Dan McKenzie, Mr. T. Guthrie, Mr. Mollison and Mr. Turner, Dr. Donelan, and others.

SECTION OF ANÆSTHETICS (Hon. Secretaries—H. E. G. Boyle Cecil Hughes): at 8.30 P.M.

Mr. Fleming: Case of Extraordinary Tachycardia.
Mr. J. H. Chaldecott and Mr. C. W. G. Bryan: Remarks on Anoci-association.
Mr. Apperly: A New Ether Junker for Nose and Throat Work.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Clinical Meeting.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8 P.M., Special Clinical Evening. Cases will be shown from 8 P.M. to 8.30 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Prof. T. R. Glynn: Hysteria in Some of its Aspects. (Bradshaw Lecture.)

THURSDAY.—5 P.M., Dr. C. A. Mercier: Astrology in Medicine. (Fitz-Patrick Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Osteoplastic Inflammation of Bone. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. M. H. MacLeod: Clinique (Skin). 5.15 P.M., Lecture:—Dr. S. A. K. Wilson: Common Errors in Diagnosis—Nervous Diseases.

TUESDAY.—4 P.M., Dr. P. Stewart: Clinique (Medical). 5.15 P.M., Lecture:—Mr. J. E. Lane: Common Errors in Diagnosis—Venereal Diseases.

WEDNESDAY.—4 P.M., Mr. G. E. Waugh: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. T. Walker: Common Errors in Diagnosis—Urinary.

THURSDAY.—4 P.M., Dr. J. S. R. Russell: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. E. Squire: Common Errors in Diagnosis—The Chest.

FRIDAY.—4 P.M., Mr. H. L. Whale: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. B. Harman: Ocular Symptoms Indicating Vascular Disease.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Mr. B. Harman: Ocular Symptoms Indicating Nerve Disease.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Mr. B. Harman: Ocular Symptoms Indicating General Septic Infection.

THURSDAY.—10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Shuter: Anæsthetics.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Dr. Owen: Practical Medicine. 12.15 P.M., Lecture:—Dr. Bernstein: Clinical Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Shuter: Anæsthetics.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.—2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.—2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.—2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Albuminuria.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.—2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Sir William Bennett, K.C.V.O.: Some Clinical Experiences.

FRIDAY.—Out-patient Demonstrations;—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.—2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford; Medicine. 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.—10 A.M., Col. Barry: Radiography.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

TUESDAY.—2 P.M., Selected Cases of Deafness (Mr. Gillies). Clinic: 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3 P.M., Selected Cases of Chronic Affections of Joints. 4.30 P.M., Lecture:—Dr. Leslie: Morbid Conditions of the Chest (with lantern demonstration).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan).

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-s reet, Piccadilly, W.

MONDAY.—5 P.M., General Meeting of Members.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

Course of Lectures on the Neuroses and Psychoses of Children:—

TUESDAY.—2 P.M., Dr. F. Warner: Motor Signs of Brain Action and Status.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4.30 P.M., Lecture:—Dr. Habershon: Bronchiectasis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Taylor: Clinical Cases.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Buzzard: Clinical Cases.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

MANCHESTER HOSPITALS POST-GRADUATE CLINIC.

TUESDAY.—SALFORD ROYAL HOSPITAL—4.30 P.M., Mr. R. Ollerenshaw: Some Common Affections of the Rectum and Anus.
WEDNESDAY.—ROYAL INFIRMARY—4.30 P.M., Mr. A. H. Burgess: Renal Tuberculosis.
THURSDAY.—ANCOATS HOSPITAL—4.30 P.M., Mr. W. H. Hey: Cancer of the Breast.
FRIDAY.—ROYAL EYE HOSPITAL—4.30 P.M., Dr. A. H. Griffith: Myopia.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICAL DEMONSTRATIONS.

TUESDAY.—ROYAL HOSPITAL.—3 P.M., Prof. Burgess: On Certain Nervous Diseases.
FRIDAY.—ROYAL INFIRMARY.—3 P.M., Prof. S. White: The Surgical Treatment of Intestinal Stasis.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Abnormal Presentations of the Fœtal Head (continued). 11 A.M., Examination of Patients and Minor Operations.
TUESDAY.—10 A.M., Major Operations.
WEDNESDAY.—10 A.M., Obstetrical Lecture: Pelvic Presentation. 11 A.M., Examination of Patients and Minor Operations.
THURSDAY.—10 A.M., Major Operations.
FRIDAY.—10 A.M., Gynæcological Lecture: Gynæcological Diagnosis (continued). 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 26th–Nov. 5th (Ghent).—International Exhibition.
Oct. 1st–Nov. 1st (London, Shepherd's Bush).—National Gas Exhibition.
,, 28th–Nov. 1st (London, Royal Horticultural Hall).—Twenty-fourth Universal Cookery and Food Exhibition.
Nov. 7th–15th (London, Olympia).—Twelfth International Motor Exhibition.

In 1914:—

April 14th–18th (New York).—Fourth Congress of the International Surgical Society.
May 1st–Nov. 1st (Lyons).—International Town Life Exhibition.
July 6th–11th (Blackpool).—Twenty-ninth Congress of the Royal Sanitary Institute.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial Staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. J. Astier, Asnières; Mr. A. Almagro, Lond.; Messrs. Arnold and Sons, Lond.; Argyle and Bute Asylum, Lochgilphead, Clerk to the; Ardath Tobacco Co., Lond.

B.—Messrs. Butterworth and Co., Lond.; Birmingham Corporation, Medical Superintendent of; Messrs. Baxter, Payne, and Lepper. Lond.; Dr. F. G. Bushnell, Plymouth; Messrs. Burroughs Wellcome and Co., Lond.; Dr. Maxim H. Bing, Budapest; Mr. Victor Bonney, Lond.; Mr. H. Butterfield, Northampton; Bury Infirmary, Secretary of; British Drug Houses, Lond.; Mr. H. Blakeway, Lond.; Bristol Royal Infirmary, Secretary of; Dr. J. B. Berkhart, Lond.; Mr. W. J. Burroughs, Lond.; Mr. P. Bouchard, Casablanca; Dr. W. Blair Bell, Liverpool.

C.—Messrs. Casein, Ltd., Lond.; Messrs. E. Cook and Co., Lond.; Messrs. C. D. Clayton, Lond.; Mr. H. A. Collins, Croydon; Messrs. J. and A. Churchill, Lond.; Camberwell Guardians, Lond., Secretary to the; County Asylum, Warrington, Clerk to the; Messrs. Cassell and Co., Lond.; Dr. L. G. Cole, New York; Messrs. Samson Clark and Co., Lond.; Chelsea Hospital for Women, Lond.; Dr. James T. Case, Battle Creek; Dr. J. M. Clarke, Lond.; Dr. E. Curtin, Bournemouth.

D.—Dr. D. Dinshaw, Ahwaz; Messrs. A. De St. Dalmas, Leicester; Dr. med. Dreuw, Berlin; Surgeon-General J. J. Dennis, R.N., Haslar; Derbyshire Royal Infirmary, Derby, Secretary of; Surgeon S. F. Dudley, R.N., Chatham; Dr. A. B. Duprey, Brasso Piedra; Mr. Henry Dickinson, Lond.; Mr. Percy Dunn, Lond.

E.—East Sussex County Council, Lewes, Clerk to the; E. K.; *The Electrician*, Lond., Manager of; East Sussex Hospital, Hastings, Secretary of.

F.—Mr. J. P. Fagan, Lond.; Dr. H. Fraser, Kuala Lumpur; Sir D. Ferrier, Lond.; Messrs. H. Fannin and Co., Dublin; Mrs. H. French, Lond.; Messrs. Harvey Frost and Co., Lond.; Mr. E. G. Foote, Sedbergh; Dr. J. S. Ferguson, New York; Mr. George P. Forrester, Darmstadt; Mr. H. Fromm, Pinner; Farringdon General Dispensary, Lond., Secretary of.

G.—Captain H. Gall, R.A.M.C., Sialkote, India; Goodwyn Institute, Memphis, Librarian of; Messrs. W. Gaymer and Son, Attleborough; Gloucestershire Royal Infirmary, Secretary of; Messrs. Grantham and Co. Reading; Mr. F. N. Grinling, Newcastle-on-Tyne; Mrs. Roger Ganfield, Shreveport; Glasgow Lunacy District Board, Gartcosh, Medical Superintendent of; Messrs. A. Gaal and Co., Lond.; Dr. W. H. Gimblett, Lond.; Sir Rickman Godlee, Bart., Lond.

H.—Messrs. Hastings Bros., Lond.; Messrs. Hoskins and Sewell, Birmingham; Messrs. Hatch, Mansfield, and Co., Lond.; Herefordshire General Hospital, Hereford, Secretary of; Major L. W. Harrison, R.A.M.C., Lond.; Mr. C. J. Hersey, Lond.; Miss E. M. Homersham, Lond.; The J. F. Hartz Co., Toronto; Dr. F. Gowland Hopkins, Cambridge; Mr. A. Hopewell-Smith, Lond.; Hertfordshire, County Tuberculosis Officer of, Hertford; Hospital for Epilepsy and Paralysis, Lond., Secretary of.

I.—Dr. M. ap Iwan, Buenos Aires.

J.—Mr. T. R. Judson, Reigate; Mr. E. R. Johnson, New York; Dr. J. D. Jungmann, Manila; Dr. J. E. L. Johnston, Yaba, ; Jenny Lind Infirmary, Norwich, Hon. Secretary of; J. P. N.; Dr. J. Johnston, Bolton.

K.—King Edward VII. Welsh National Memorial Association, Cardiff, Secretary of; King Edward VII.'s Hospital, Cardiff, Secretary of; Mr. J. H. Kile, Sweetwater, U.S.A.; Professor W. W. Keen, Philadelphia.

L.—Dr. J. Love, Brighton; Messrs. Lea and Febiger, Philadelphia; London Press Exchange, Lond.; Leicester Borough Mental Hospital, Medical Superintendent of; London County Asylum, Lond., Clerk to the; Messrs. R. T. Lang, Lond.; Lindsey County Council, Lincoln, Clerk to the; Mrs. L. Leverson, Crowborough; London County Council, Deputy Clerk of; Dr. C. Edgar Lea, Manchester; Mr. H. K. Lewis, Lond.; Messrs. Lee and Martin, Birmingham; Dr. L.; Liverpool Medical Institution Secretary of; Dr. J. Minehead Little, Lond.; London Lock Hospital and Rescue Home, Board of.

M.—Dr. F. F. MacCabe, Calcutta; Mr. R. D. MacGregor, Lond.; Manchester Ear Hospital, Secretary of; Mr. R. Mosse, Berlin; Messrs. Z. P. Maruya and Co., Tokyo; Medical Correspondence College, Lond., Sec. of; Manchester Royal Infirmary, Secretary of; Dr. S. G. Moore, Huddersfield; Dr. Spencer Mort, Lond.; Professor Gustav Mann, New Orleans; Messrs. Mather and Crowther, Lond.; Dr. McConnel, Lond.; Lieutenant-Colonel J. J. de Zouche Marshall, Thames Ditton; Medico-Psychological Clinic, Lond., Secretaries of; Dr. Douglas D. Malpas, Biarritz; Mr. J. H. Montague, Lond.; Medical Sickness and Accident Society, Lond., Secretary of; Dr. C. D. Musgrove, Penarth; Midland Medical Society, Birmingham, President and Council of; Dr. A. S. Morton, Lond.; M.A., M.D., F.R.C.S.; Dr. F. W. Mott, Lond.

N.—Mr. H. Needes, Lond.; New York Pharmaceutical Co., Bedford Springs; Mr. W. Gifford Nash, Bedford; National Food Reform Association, Lond., Secretary of; National Health Insurance Commissioners, Lond., Secretary to; National Dental Hospital, Lond., Staff of.

P.—Messrs. G. Pulman and Sons, Lond.; Dr. W Pick, Vienna; Captain Parkinson, R.A.M.C., Lond.; Dr. C. H. Allon Pask, Eccles; Mr. F. H. Preston, Lond.; Mr. Bilton Pollard, Lond.; Penal Reform League, Lond.; *Popular Mechanics' Magazine*, Chicago; Dr. Sigismund Peller, Vienna; Pharmaceutical Society of Great Britain, Lond., Secretary of; Dr. Herbert Peck, Chesterfield; Mr. A. L. Powell, Leeds; Dr. J. J. Pringle, Lond.

Q.—Queen's Hospital, Birmingham, Secretary of.

R.—Royal Free Hospital, Lond., Secretary of; Dr. H. Robinson, Lond.; Royal Mineral Water Hospital, Bath, Secretary of; Royal Institute of Public Health, Lond., Secretary of; Reading Corporation, Clerk to the; Royal Medical Benevolent Fund, Lond., Hon. Secretary of; Royal Society, Lond., Assistant Secretary of; Royal Institution of Great Britain, Lond.; Royal Dental Hospital of London, Secretary of; Dr. Henry Robinson, Lond.; Mr. Paul B. Roth, Lond.

S.—South Devon and East Cornwall Hospital, Plymouth, Secretary of; Messrs. G. Street and Co., Lond.; Sheffield Royal Infirmary, Secretary of; Scarborough Hospital, Secretary of; Mr. J. E. Sharpe, Hull; Dr. Halliday Sutherland, Lond.; Dr. Myer Solis-Cohen, Philadelphia; Messrs. W. H. Smith and Son, Lond.; Salford Royal Hospital, Secretary of; The Scapa Society, Lond., Chairman of Committee of; Mr. G. E. Snowball, Lancaster; Mr. W. G. Sutherland, Manchester; Society of Apothecaries of London, Secretary of; Professor Wm. Stirling, Lond.; Dr. Lauriston E. Shaw, Lond.; Dr. Knowsley Sibley, Lond.; Dr. H. Oswald Smith, Sanderstead.

T.—Thompson Yates Laboratory, Liverpool, Librarian of; Messrs. W. Thacker and Co., Lond.; Technical Press, Vancouver, Manager of; Dr. John C. Thresh, Chelmsford.

U.—University of Wales, Cardiff, Registrar of.

V.—Messrs. Van Houten, Lond.; Dr. John Vassalli, Baltimore; *The Vaccination Inquirer*, Lond.; Victoria Hospital and Dispensary, Worksop, Secretary of; Dr. George H. Varley, Lond.

W.—Messrs. F. Williams and Co., Lond.; Messrs. A. J. Wilson and Co., Lond.; Western Skin Hospital, Lond., Secretary of; Mr. J. Williams Bradford; Mr. R. L. Wason, Southampton; West Riding Asylum, Burley-in-Wharfedale, Clerk to the; Captain W. P. Gould Williams, I.M.S., Blair Athol; Mr. Harry Winfield, Smithers; Mr. H. M. M. Woodward, Lond.; Mr. A. Wander, Lond.; West Bromwich District Hospital, Secretary of; West End Advertising Agency, Lond.; Dr. S. A. K. Wilson, Lond.; Messrs. J. White and Co., Chester; Mr. Charles Wray, Lond.; Mr. M. Wilson, Lond.

Z.—Dr. Angelo Zucchi, Venice.

Letters, each with enclosure, are also acknowledged from—

A.—Messrs. Abrahams, Lond.; Messrs. Arrowsmith, Bristol; Army and Navy Male Nurses' Co-operation, Lond., Secretary of; Mr. E. Arnold, Lond.; Mr. D. Armour, Lond.

B.—Mrs. Bailey, Crewe; Barnwood House Hospital, Gloucester, Medical Superintendent of; Birmingham University, Secretary of; Mr. C. A. Ballance, Lond.; Mr. E. Blatchley, Lond.; Barnsley Hall Asylum, Bromsgrove, Clerk to the; Messrs. J. Beal and Sons, Brighton; Dr. R. P. Ballard, Bradford; Bristol Royal Hospital for Sick Children, &c., Secretary of; British Oxygen Co., Lond.; Bolingbroke Hospital, Lond., Secretary of.

C.—Canterbury Borough Asylum, Clerk to the; Messrs. Carrane and Shawcross, Wellington; Messrs. Carnrick and Co., Lond.; Messrs. Cordes, Hermanni and Co., Hamburg.

D.—Dumfries and Galloway Royal Infirmary, Secretary of; Messrs. Dowie and Marshall, Lond.; Dorset County Asylum, Dorchester; Denver Chemical Manufacturing Co., Lond.; Dorland Agency, Lond.; Messrs. Duncan, Flockhart and Co., Edinburgh; Messrs. W. Dawson and Sons, Lond.

E.—Mr. W. P. Everard, Athlone; Messrs. Ewart, Seymour, and Co., Lond.; Messrs. Elliott, Son, and Boyton, Lond.; E. C., Kew.

F.—Messrs. Fryer, Cooper, and Co., Lond.; Fellows Co., New York.

G.—Dr. M. Graham, Madeira; Dr. J. Glen, Grangetown; General Life Assurance Co., Secretary of; Galton Laboratory, Lond., Hon. Secretary of; Mr. E. H. Godbold, Lond.; Mr. J. H. Goring, Lond.; Dr. L. Guthrie, Lond.; Dr. A. H. Gregson, Blackburn; Mr. A. D. Griffith, Lond.

H.—Messrs. Hogg and Son, Lond.; Harley Institute, Lond.; Dr. H. W. Hake, Lond.; Lieutenant P. Hayes, R.A.M.C., Poonamallee; Hereford County and City Asylum, Clerk to the; Dr. H. R. Harrower, Lond.; Dr. B. Hall, West Mersea; Hawkhead Asylum, Paisley, Medical Superintendent of; Mr. W. Houghton, Lond.

J.—Mr. H. A. Jeffery, Bradford; J. D. W.; J. M. G.; J. H. C.; J. C.; Mr. F. J. Joynes, Dursley; I. E.

K.—Miss Knaggs, Southport; Dr Kennedy, Lond.; Kensington Dispensary, Lond., Secretary of; Miss A. D. Kerr, Tauranga; Messrs. D. J. Keymer and Co., Lond.

L.—Mr. T. S. Logan, Stone; Messrs. Lee and Nightingale, Liverpool; Leeds General Infirmary, Treasurer to the; L. L.; Leicester Royal Infirmary, Secretary of.

M.—Mental Nurses' Co-operation, Lond., Secretary of; Manchester Corporation, Treasurer to the; Messrs. May and Williams, Lond.; Maltine Manufacturing Co., Lond.; Nurse Moore, Lond.

N.—Norfolk Education Committee, Norwich, Accountant to the; North Witchford Union, March, Clerk to the; North Ormesby Hospital, Middlesbrough, Secretary of; Mr. T. North, Lond.

O.—Mr. A. B. C. Orchard, Darlington; Dr. C. Oldfield, Leeds; Messrs. Osborne and Co., Lond.; Mr. E. Owen, Lond.

P.—Dr. A. M. Pryce, Margate; Dr. M. Philip, Lond.; Mr. F. T. Pain, Lond.; Price's Patent Candle Co., Lond., Secretary of.

R.—Royal Hampshire County Hospital, Winchester, Secretary of; Messrs. Rebman, Lond.; R. M. L.; Messrs. Roberts and Co., Lond.; Dr. P. B. Ridge, Lond.

S.—Mr. A. W. Statter, Eastleigh; Dr. Purves Stewart, Lond.; Stockport Infirmary, Secretary of; Messrs. W. H. Smith and Son, Birmingham; Lieutenant-Colonel Sunder, I.M.S., Bankipur; Stretton House, Church Stretton, Medical Superintendent of; Springfield House Asylum, Bedford, Medical Superintendent of.

T.—Dr. Wu Lien Teh, Harbin; Dr. J. P. Tildesley, Willenhall.

V.—Messrs. J. W. Vickers and Co., Lond.

W.—Dr. A. A. Warden, Paris; Warneford Hospital, Oxford, Medical Superintendent of; Miss M. B. Wigan, Lyddesdown; Mr. W. C. Wigan, Likoma; Wolverhampton, &c., General Hospital, Secretary of; Messrs. W. Wood and Co., New York; Waldorf Bindery Co., St. Paul; Woodhall Spa Co., Woodhall Spa, Secretary of; W. M. M. J.; W. E. G.; W. C. H.; W. H. C.; West Suffolk General Hospital, Bury St. Edmunds, Secretary of.

Y.—Dr. C. C. Yount, Ancon, Panama.

An Address
ON
HEREDITY AND INHERITANCE AS THEY CONCERN THE PHYSICIAN.

Delivered before the Birmingham Society for the Study of Heredity

BY CHARLES MERCIER, M.D. LOND., F.R.C.P. LOND.

MR. PRESIDENT AND GENTLEMEN,—I take it that in inviting a physician, whose profession embraces a very outlying region of biology, to address you on the central theme of this science, which is not his proper subject, and as to which he is an outsider, your object is to learn what bearing the great problems of heredity and inheritance have upon the practice of the physician; how far they influence his views of the nature of disease; how far they modify in his opinion the fate of his patients; and how far and in what way he takes them into account in the advice he gives. This, I say, is my surmise; but it may be that you merely had in your minds an address that I gave in this city a year ago, and based your invitation on the ground that however erroneous the doctrine might be, you would at least hear something racy. If this was your intention I am afraid you will be disappointed. I have nothing to tell you that is not quite humdrum and not much that you have not heard before.

As I have said, I am not an expert in that central realm of biology that includes the problems of heredity and inheritance; but at the same time, in my capacity as a physician engaged in the treatment of mental disease, I have constantly to take these problems into account, for it is impossible, I will not say to understand these diseases, for I do not profess to understand them, but it is impossible in many cases to form a trustworthy opinion or to give trustworthy advice without taking heredity and inheritance into account.

EUGENICS.

We hear a great deal nowadays about eugenics, and some of us hear so much about it that we get rather tired of aspirations, praiseworthy, no doubt, but for the most part extremely vague, for the coming of a millennium in which marriages will be arranged by a committee of experts—an expert, I may explain, is a person who is omniscient on one subject and knows very little about any other: I ought to know, for I am myself an expert—a committee of experts on human breeding. Breeders of livestock breed for the most part for single qualities or for simple combinations of qualities—they breed cows with an eye to milking capacity, steers for rapid growth and early maturity, poultry for feather and comb, or perhaps for laying fertility, hounds for speed and scent, and so forth; but the controllers of eugenics in the human race are to breed for a vast number of complex qualities, and to breed for them all at once. They are to breed for physical robustness and capacity to resist disease, for physical beauty, for moral elevation, for intellectual genius, and manual dexterity; the representative of the army on the board of eugenics will insist on breeding for courage and bellicosity; the representative of the navy for agility and immunity from sea-sickness; the representative of commerce will look to pushfulness and skill in bargaining; the representative of the Church will breed for ability to conduct clubs for working men and mothers' meetings; the representative of art will breed for ability, if not to paint pictures, at least to buy and pay for them; and all will combine to produce a breed of physicians who will practise without desiring fees. I speak with confidence and with knowledge of the subject when I say that some of these ideals are impracticable. No one has greater faith in eugenics than I have, especially when eugenics is spelt with a large E and is controlled by the State. We see in everything, from the treatment of suffragettes to the administration of the telephones, how vastly superior is State regulation to the enterprise of private individuals.

A Hypothetical Case as to the Expediency of Marriage.

Eugenics has a peculiar interest for me, because I am often asked to advise on the expediency, from an eugenic point of view, of a marriage. I have no reason to believe that my advice is ever taken, but it is often asked for, and sometimes even paid for, and therefore I have no reason to complain. It sometimes happens, and cases of the kind may have come under the observation of some of those here present, that a young man, who may even be middle-aged, becomes enamoured of a young woman to such a degree that he becomes engaged to marry her. And it sometimes happens—and again some of you may be able to corroborate my statement—that after a certain length of engagement he realises the truth of that wise prediction expressed by a neighbouring nation in the well-known words:—

> Tu t'en repentira, Colin,
> Tu t'en repentira;
> Car si tu prends une femme, Colin,
> Tu t'en repentira.

In such a case several courses are open to the penitent. He may flee to foreign parts; he may stand the racket of an action for breach of promise; or he may, and often does, come to me and say: "Doctor, I have conscientious scruples. My family positively reeks of insanity. My father's second cousin's first husband drank a barrel of beer a day, and ended his life by spontaneous combustion. This being so, is it not certain that if I marry dear Jemima Brown I shall certainly go raving mad and cut her into little bits? At the present moment I feel so frightfully nervous that if you give me a certificate to this effect I feel confident that I shall so far forget myself as to double your fee." These may not be his precise words, perhaps, but this is the purport of the confidences that I sometimes receive when I am asked to give an opinion on an individual case of eugenics.

The Biometric and Mendelian Methods.

My rule is to decide all cases on general principles, and in accordance with this rule I consult the works of acknowledged authorities for guidance. First I turn to that eminent statistician and biometrician Professor Karl Pearson, and I obtain from him the following apt information: Supposing X to be the character in the parent, and Y the mean character in the offspring, then the equation is

$$Y = A + B \cdot X,$$

where A is a dimension of the same nature as X or Y, and B is a number that will vary from case to case. My difficulty is to know what particular variation of B applies to the case before me; and as Professor Karl Pearson tells me nothing about this, I am unable to apply the formula, and am obliged to turn to his rival and antagonist, Professor Bateson, to see what light the laws of Mendel will throw upon my difficulty.

From Professor Bateson I learn that when a dominant is crossed with a recessive the offspring will all exhibit the dominant character; but in the next generation the dominants will be to the recessives as 3 : 1, and of the three dominants only one will be a pure dominant, the others having the recessive character latent. It is perhaps my density which prevents me from learning from these premisses whether the fact of his father's second cousin's first husband's having drunk a barrel of beer a day will cause Mr. Jones to cut Jemima Brown into little bits in case they should be united in the bonds of holy matrimony. Perhaps it is my density, and I may be unduly biassed in my own favour when I decide that it is not, and that neither the laws of Mendel nor the equations of biometry are of the slightest value in the determination of individual cases. It is manifest on the face of them that they cannot be, and for this reason. The methods of Galton and Pearson are applicable to large numbers, and to large numbers only, and do not yield results that are even approximately true until the numbers become very large. To apply biometrics to individual cases is much like comforting a convicted and condemned murderer by saying, "Cheer up! There are only 15 persons hanged every year in this country out of a population of 40 millions; so that it is 2,666,666·6, &c., to 1 that you won't be hanged!"

The Mendelian method of Professor Bateson is equally inappropriate. It tells me that if the father of my patient was a drunken lunatic, and his mother was a paralysed dement, and if the father's drunkenness is dominant and lunacy recessive, while in the mother paralysis is dominant and dementia recessive, and if they have 16 children, then the chances are that nine children will be paralysed drunkards, three will be demented drunkards, three will be paralysed lunatics, and one will be a demented lunatic. This is very interesting, but it is not what I want to know

I want to know what the chances are that poor Jemima Brown will be cut into little bits in the improbable event of her compelling Mr. Jones to marry her.

Inutility of Biometrics and Mendelism to the Practising Physician.

I have chosen an outside case to illustrate the thesis that I wish to establish, which is that neither biometrics nor Mendelism is of the slightest value to the practising physician. Mendelism has proved its utility in another field by enabling breeders to produce certain strains of wheat and other stock that could not have been produced, or could not have been so rapidly produced, without its aid; and biometrics has no doubt its value in another field by showing the general trend of variation in a large population; but neither of them can be applied to individual cases, and as it is with individual cases that the physician is concerned, neither of them has the slightest value for the physician, and as a physician he is no better off than if Galton and Pearson and Mendel and Bateson had been untimely births which never saw the light.

Seeing that I have already declared that a physician practising in mental disease cannot practise efficiently without taking into account both heredity and inheritance, and seeing that I have now declared that the two accepted—and may I say fashionable?—methods of investigating the facts of heredity and inheritance are quite useless to him, the question arises, What is his attitude to these problems? How does he take them into account? What are the aspects of them that he has to consider?

THE NATURE OF REPRODUCTION.

In order to answer these questions I must lay before you two hypotheses, I think I may go so far as to call them theories, of my own, which I formulated nearly a quarter of a century ago, and which have received, as far as I know, no attention at all, though both are of immediate practical importance. For some reason or other no one takes my doctrines seriously; at any rate, until they are adopted by some German, and are reintroduced into this country as made in Germany.

Characters of Germ and Sperm Cells.

My first proposition is this: Setting aside parthenogenesis, the alleged cases of which that come before the physician being found on investigation to be mythical, all reproduction is due to the union of a male element with a female element—of a sperm cell with a germ cell. My hypothesis is that the contributions of these two elements to the product differ in this way: the female element contributes the substance or matter of the offspring; the male element contributes the force or energy that animates the matter. The female element is the coals in the grate; the male element is the match that sets them alight. The female element is the great mass of dough in the kneading-trough; the male element is the little bit of yeast that leavens the whole lump and sets it all fermenting. The evidence in favour of this view seems to me overwhelming. In the first place, the disparity in bulk of the two elements is very great. The egg cell is of appreciable magnitude. In many organisms it is even visible to the naked eye. The sperm cell is excessively minute. In some cases the disparity is as great as 100,000 to 1. In the beginning and from the beginning, therefore, the female element does, in fact, contribute substance or matter out of all proportion to the amount contributed by the male. In the second place, the female element is lethargic and non-locomotor. It has no power of spontaneous movement, or even of change of shape. The only evidence of life that it gives is the preservation of its structural integrity, which is but brief, and its growth, which soon comes to an end. Its part is vegetative—anabolic. The sperm cell is the very opposite of this. It is extraordinarily active. It is rapidly locomotor. It incessantly changes its shape. Its life, which is prolonged, is one of eager, strenuous, and incessant activity. It is the very embodiment of energy.

The Developmental Impetus given by the Sperm Cell.

Now note the result of their union. Before it is fertilised, or as I should rather say energised, by the sperm cell, the germ cell has an inert and vegetative existence. As it is alive, it must contain some stored energy or motion, for this is the character of all living things, but the motion that it contains is potential only, and is consumed internally in making and conserving additions to its bulk. Very rarely does the mammalian ovum even undergo a single segmentation or division previous to impregnation, and if left unimpregnated it soon dies, and dies, I suggest, because the amount of motion it contains is insufficient to hold the mass in equilibrium against the action of incident forces. It dies for the same reason that a top falls when it ceases to spin. But now what happens when the minute mass of the sperm cell—a mass altogether insignificant in proportion to that of the ovum—is incorporated in its substance? At once the whole mass is infused with energy. It becomes the seat of active and incessant change. It segments and resegments incalculably. It receives, in short, an impetus that carries it forward for years upon the path of growth and of development. It is this view of conception, that regards it as the reception by the germ of an impetus to growth and development, that is so important and so fertile in the field of mental pathology. I do not deny that the germ contains within itself its own potentiality of development any more than I deny that the mass of coal in the grate contains its own potentiality of burning. Nor do I deny that the speck of matter in the sperm cell contains its own potentiality of indefinite multiplication, so that it may permeate the whole bulk of the organism, however many million times that organism may increase in bulk. I do not deny this any more than I deny that the grain or two of yeast may multiply so as to permeate the sponge in every part. And both the potentiality of the germ to develop and that of the sperm to multiply are important; but the supreme, the vital, the central fact in conception is the impetus given by the sperm to the germ, an impetus that carries the product along the path of growth to adulthood and maturity, and along the path of development until its gradual failure marks the onset of senility. It is this tremendous impetus that matters to the physician for mental disease.

The Implications of the Doctrine.

For note the implications of this doctrine and see how important they are. If you kick a football, or strike a billiard ball with the cue, or a cricket ball with the bat, you give that ball an impulse. You communicate to it an impetus. You send it flying along a path that is predetermined by the conditions. Now, this is the important thing—the distance the ball travels depends, other things being equal, upon the impetus that you communicate to it. If you hit it hard it will go far; if you hit it less hard it will go less far. It is the same with the developmental impetus that is given to the germ at conception. If the impetus is a powerful one, the germ will travel far upon the predetermined path of development and growth; if the impetus is less powerful, the germ will travel less far. If the impulse communicated by the sperm is sufficiently powerful, it will make a boundary—it will reach the boundary of the normal. If it gets a tremendous swipe, it will go far over the boundary and become the lost ball of genius. If the impulse it receives is deficient in vigour, it will not reach the boundary, but will fall short of it by a space that will be greater or less according as the impulse is more or less lacking in vigour. The impulse may expend itself in reaching early childhood, or it may suffice to attain late childhood, youth, or adolescence, and according as the development of the brain ceases at one or other of these stages, the result is idiocy, or imbecility, or feeblemindedness, or mere dulness, as the case may be.

Two important qualifications must be made here. In the first place, insufficiency of the developmental impetus is not the only cause of deficiency of mind; in the second, deficiency of mind is not the only result of a defective conceptual impetus. Original deficiency of mind, of whatever degree, from idiocy to dulness, always arises from premature cessation of the development of the brain. This needs no demonstration. It is manifest on the face of the facts. But premature cessation of development may be brought about in two ways. When a cricket ball is driven by the bat it sometimes fails to reach the boundary, and the reason it does not reach the boundary may be that it was not driven hard enough; but it may be that it was driven hard enough, but on its way to the boundary it came in contact with some obstacle, say the hand, or the head, or the abdomen of a fielder, and its course was thus brought to an abrupt termination. Similarly, the development of the brain may cease from premature exhaustion of the developmental

impetus, or it may be brought to a more or less sudden close by the intervention of some external agent which forcibly arrests it; and each of these methods is answerable for some cases of mental defect. The accidental intervention which puts a stop to the development of the brain may be a violent blow on the head, or it may be an inflammation of the membranes, or it may be the poison of some specific fever. All these may be said to have been proved by specific instances, but it is clear also that for a full development of the brain it must have an adequate supply of appropriate nourishment; and it is possible, and even probable, that some addition is made to the ranks of the mentally defective by those who are seriously underfed at the time the brain is actively developing. I say seriously underfed, for there is some evidence that the brain is not only greedy but masterful, and that it addresses to the rest of the body that straightforward and downright Dunstable maxim which we may term eutrophic, and which might well be written over the doors of the Chancellor of the Exchequer: "Thou shalt want ere I want." And I say underfed during the time the brain is actively developing because, although the brain goes on developing in some respects until it begins to deteriorate, its development does not proceed continuously. It goes by fits and starts; and this brings me to my second doctrine, which, like the rest of my teaching, has but a single adherent.

Direction of Developmental Impetus into Two Channels.

The doctrine is this: that after a certain primitive stage of development is reached, it proceeds in two paths, which are complementary to one another, and to some extent inversely proportional to each other. However great the developmental impetus may originally have been, it is limited in amount; and if it is directed into two channels, then the more that flows into one channel the less there is at the service of the other. Those of you whose houses are still lighted by gas will know that at certain hours the gas, which had been burning quietly and steadily, begins to flare and sing, and you account for the change when you remember that at that hour the public-houses close, and a large expenditure of gas is suddenly shut off, leaving an increased pressure at the service of those who are still using it. There is another illustration that I am in the habit of giving. Everyone now knows that gardeners sometimes grow fruit trees consisting of but two stems growing from a single stock. These two stems or branches are fed from a single source of nourishment, which is limited in amount, and it is clear that the more that is attracted to one stem the less there is at the service of the other. Gardeners know of several expedients by which the flow of sap may be regulated and equalised so that neither branch shall grow at the expense of the other. Now if you carry this notion in your minds you will see what I mean when I speak of mere growth in bulk and of development in complexity being complementary to one another, so that the one proceeds at the expense of the other. The more of the developmental impetus or energy that goes to build up bulk of body, the less there remains to produce complexity of development, and *vice versâ*. Now the only organ that at birth is greatly wanting in complexity of development is the brain. All the rest are then almost complete, and thereafter grow in bulk alone, so that after birth the two great competitors for the single supply of developmental energy are bulk of body and complexity of brain; and complexity of brain stands roughly for development of intelligence. If the supply of energy is of average amount, and if it is shared in equable proportion between these rivals, the result will be a brain of average ability in a body of average size; but several modes of departure from this norm are possible, and are exemplified in experience.

Supposing the supply of energy to remain about the average, but the brain attracts more than its due share, the result will be exceptional ability in a person of less than average stature; and you will recall how many men of the highest intellectual eminence have been below the average height. I need only instance five of the greatest commanders in history—Cæsar, Marlborough, Nelson, Napoleon, and Wellington.

If, the supply of energy remaining normal, growth in bulk attracts an undue share, the result will be a brain of little power in a huge body; and it is notorious that giants are more often below the average in ability than persons of ordinary stature. They are not necessarily so, however, any more than dwarfs are necessary geniuses, for a clever giant may be produced by the equable distribution of an exceptionally large store of developmental energy, and an idiotic dwarf is quite frequent from what we may suppose is the opposite condition.

There are no known means of adding to the developmental impetus or energy once conception has taken place, but I have no doubt that the amount of this impetus can be materially modified by what takes place before conception, and there is no doubt that the proportions of it that go to increase of bulk and to development of intelligence respectively vary from time to time in the same person.

Precocious Children.

Hitherto I have spoken as if increase in bulk of body and increase in brain development proceeded equally and *pari passu*, but anyone who has watched the growth of children knows that this is rarely or never the case. Precocious children are common enough, and the precocious child is always small for his age; his brain has developed at the expense of his body. For a time the brain develops alone and growth in stature is stationary, and if this period is prolonged the child may become a marvel of precocity. One fond mother confided to me that she should give her child a special education to fit him for the only career that seemed worthy of his marvellous ability—that, namely, of Prime Minister. He was then 6 years old. Now he is the father of a family, and though of fair average business ability, he is not yet Prime Minister, and for my own part I should hesitate to entrust the destinies of the nation to his hands. His history is the history of scores of other precocious children. From five or six to seven or eight they are prodigies of learning and intellectual vigour. They are always top of their class in school, and they bring home prizes in heaps. But after a certain period of uninterrupted success at school and of stationary growth—they are always small for their age—they begin to fall behind. Others, previously their inferiors, catch them up and overtake them. They go down and down in the class lists until their parents' hopes are dashed, and even the medical man may be consulted to know if their brains are not giving way. But it is all right. The medical man, if he knows his business, will decide the matter by the measuring rod and the scales. He will notice that the child has begun to grow. He is shooting up by leaps and bounds. His trousers are too short, and his wrists project from his sleeves. By some means, perhaps by the product of some ductless gland, the developmental energy has been switched off from his brain and switched on to his body. Either there is not enough to serve both at once, or the regulating apparatus acts alternately, now one channel being opened and the other shut, and now the conditions being reversed. After a period in which growth proceeds apace, and intelligence seems actually to diminish, the conditions are either reversed again, or more often a better balance is established, and the two proceed together in harmony; but children who have been violently precocious never, in my experience, completely recover the check to growth in stature that they receive during their precocity.

Practical Conclusions.

From these observations several consequences follow. In the first place, if a child is very precocious it is never safe to predict that it will set the Thames on fire. I say nothing about musical prodigies or calculating prodigies, because music and mathematics, like chess, and linguistics, and certain other faculties, have no relation to general ability. They may be highly developed in the dull, and they may be absent in exceptionally clever men. They go for nothing. In the second place, when a hitherto intelligent child becomes stupid, dull, clumsy, and even when it exhibits mental traits that are distinctly abnormal and alarming, we need not be much concerned if we find that it has started into rapid growth; and if the growth is very rapid almost any mental symptom may be witnessed without alarm. In the third place, we need not fear ill results from stimulating the intelligence of a child, even of a precocious child, provided it is healthy in body, eats well, sleeps well, and is not disturbed by dreams, and provided we do not continue the stimulation into the period when bodily growth has started and the development of mind has no backing. The week that the child starts into growth all stimulation of

the intellect should cease; and when the growth is rapid intellectual exertion should be restricted, and watched with vigilance. Especially if there is in the family any tendency to nervous or mental disorder, children who are growing very rapidly should be withdrawn from school altogether until the period of rapid growth is over. If I had charge of a school I should measure and weigh the children frequently, and should regulate their intellectual exertion according as growth was active or quiescent. I do not think that intellectual work at high pressure is harmful to either boys or girls as long as food, sleep, and bodily exercise are sufficient; but I am quite sure that pressure of intellectual work in those who are growing rapidly should never be permitted; and if growth is proceeding very rapidly, all intellectual work should be put aside. Another thing that requires careful regulation is the diet. It is scarcely possible to give growing children too much to eat, and it should always be borne in mind that the carbohydrates—starch, sugar, and fat—are mainly fuel that is burnt up in producing muscular movement, and that the proteins are the main elements in the formation of tissue. Consequently, it is a mistake to restrict the meat ration of children.

THE CONTINUITY OF THE GERM PLASM.

To go back now to my supposition of the several parts taken by the sperm cell and the germ cell in producing the development of the organism. If my view is correct, that conception is the production of an impetus towards growth and development, then, manifestly, it is desirable that this impetus should be as vigorous as possible; and this maximum of vigour can only be produced by a sperm cell charged to the full with energy uniting with a germ cell that is at any rate not deficient. The commonplace view taken by the commonplace man and shared by all breeders of stock is that the more vigorous the parent the more vigorous will the reproductive cells of that parent be, and that the best offspring are the product of the healthiest parents. Great doubt must be thrown upon this opinion if we are to accept Weismann's hypothesis of the continuity of the germ plasm, and all the implications of that hypothesis that are held by his disciples, whose enthusiasm has carried them, as the enthusiasm of disciples so often does, far beyond the position of their master. It is this habit that reconciles me so completely to the knowledge that I have no disciples. Weismann's hypothesis is that very soon after conception certain cells formed by the division of the zygote are set aside to form the reproductive cells of the new organism, and I do not know that it is anywhere positively and clearly stated—clearness is not such a foible with biologists as positiveness is,—but it is generally assumed that after the reproductive cells are set aside, nothing that happens to the soma, or body cells, has any influence or effect whatever on the reproductive cells. These latter are in the body, but not of it. They lead an independent life, and are exempt from any consequences of anything that may happen to the soma. They live apart like—

> The gods who haunt
> The lucid interspace of world and world
> Where never creeps a cloud or moves a wind,
> Nor ever falls the least white star of snow,
> Nor ever lowest roll of thunder moans,
> Nor sound of human sorrow mounts to mar
> Their sacred everlasting calm!

I do not say that this doctrine is taught exactly in these terms, but one rises from the perusal of the writings of the Weismannites with this impression strongly on one's mind, and I venture to say that whether the continuity of the germ plasm is a correct doctrine or not, this extension of it is without doubt erroneous. Even the most devoted adherent of the continuity of the germ plasm and its sequestration from the soma must admit that when the body dies the reproductive cells that it contains also die; and can scarcely contest that when the body is sick unto death the reproductive cells can scarcely retain the full vigour that they had when the body was in robust health. I am quite willing to grant that they have a certain independence, and do not respond to every trifling and temporary impairment of the bodily health. No doubt they have considerable inertia in this respect, and follow the fluctuations of bodily health sluggishly, and, as it were, unwillingly, but that they do follow the fluctuations when the fluctuations are extreme is shown by the fact that the death of the body is followed at no long interval by the death of the reproductive cells. It is fair to infer that if the reproductive cells follow slowly and sluggishly the deterioration in the health of the body, they will follow with equal deliberation its recovery, and we may fairly suppose that children begotten after prolonged illness, even some time after, will be deficient in stamina. I think there is clinical evidence that this is so, and there is another sequence of which I am sure, and that is that children born at the extreme end of childbearing life are frequently less vigorous both in body and mind than their elder brothers and sisters, and are not infrequently dwarfed in body or mind or both. I have seen instances that leave no doubt in my mind that a very late conception may result in imbecility in the offspring, and it is notorious that children born near the climacteric of the mother are often not viable. The late Dr. Langdon Down was of opinion that one cause of idiocy and imbecility is the drunkenness of the father at the time the child was begotten. *A priori* I should think this extremely unlikely, for drunkenness is but a temporary intoxication, and temporary alterations in the soma cannot be expected to influence the reproductive cells. Moreover, when we remember the almost universal drunkenness that prevailed in the time of the Regency in this country, it is difficult to account on this hypothesis for the extraordinary increase in the general level of intelligence that characterised the reign of Queen Victoria.

It may seem scarcely worth while to present a formal argument to show that if we want vigorous children we must provide healthy parents, for this seems sufficiently obvious, and oddly enough is preached as loudly by those who adopt in its extreme form the doctrine of the sequestration of the reproductive cells as by practical breeders of stock; nevertheless, it is always pleasing, if it is not always useful, to point out an inconsistency.

INHERITANCE IN RELATION TO INSANITY.

So much for that part of the subject: and now, leaving heredity, let us inquire what interest inheritance has for the physician, at any rate for the physician who practises in nervous and mental disease. It is a commonplace, both in the world of medicine and in the world outside of medicine, that insanity runs in families; and undoubtedly we often find other instances of insanity in the families of our insane patients; but this is only a small part of a large truth. We must take it in connexion with two other facts that are not less important. It is quite true that in a family that has one insane member we often find other members that are insane; but it is equally true that in these same families we find also other members who do not exhibit a trace of insanity or of any other disorder of the brain; and we find yet other members who are not indeed insane, but who suffer from some disorder of the functions of the brain. In these families we find some members who are hysterical, some who are epileptic, some who have outbreaks of unprovoked temper, others who will sulk for days and weeks, others who carry jealousy to crazy excess, others who cultivate the moral torture of their families into a fine art, others who suffer from agoraphobia or claustrophobia, from obsession or imperative idea, or from paroxysmal drunkenness.

All these disorders are disorders ultimately of the highest functions of the brain. They are disorders of a region of grey matter of very wide extent, of very various function, and of excessively complex organisation. The idiot, the imbecile, and the feeble-minded never attain the necessary complexity of organisation, and remain for life without struggle or protest complacently in the condition of children or even of infants. But there are others who go farther than this. They grow up normally to adolescence, and it is not until adolescence is reached that the heavy burdens of life are assumed and the conscious struggle for life begins. In the nursery and the school the conditions of life are artificially simplified to adapt them to the simple minds of children, youths, and girls; but when the adolescent leaves school he goes, as we call it, "out into the world." He may not be compelled to earn his own livelihood, but he comes into close relation with the infinite complexity of modern civilised society, he is no longer schooled and tutored, but has to make his own decisions about serious affairs under the guidance of his own reason. Just at this time, too, the reproductive activity asserts itself. A great body of emotion is added to the internal turmoil, and the stress is too great for an imperfect organisation. The brain falls into disorder

upon being confronted with problems with which it is unable to cope, just as we may suppose the town council of Birmingham would fall into disorder if it were suddenly called upon to administer the British Empire. There is a struggle, but a futile and ineffectual struggle. There is neither personnel nor moral enough for the task; and after a brief period of active mania the patient settles down into weakmindedness or imbecility, from which he may emerge, after a long rest for recuperation and reconstruction of the brain, or in which he may remain for the rest of his life. This seems to be a premature cessation of development comparable with idiocy and imbecility, but occurring at a later stage; but clinically they differ, for while there is very little evidence that idiocy, imbecility, and weakmindedness are heritable, in the sense that they are passed on from parent to child, cases of adolescent insanity do usually occur in families in which there are other insane members.

Inheritance of Nervous Instability.

For my own part, I do not believe that insanity is ever inherited. What is inherited when nervous disorder of this and other kinds appears in successive generations, is a certain instability or vulnerability of the nervous structure in the highest regions of the brain, such that they readily become disorganised when exceptional demands are made upon them, or even when demands are made upon them that are not exceptional. The nerve tissue in these parts of the brain is of extreme complexity, the area over which it is spread is large, and its functions are various. The chief thing they have in common is that one and all are substrata of mind—that is to say, that during the activity of any part some form or phase or faculty of mind is active. Owing to their large area, it may easily happen that one part is disordered in its working while other parts remain normal and carry out their functions faithfully, and according as one part or another is disordered, according as the disorder spreads in area or in depth, according as the spread is rapid or slow, so do the symptoms vary. These are all accidents of stress or of circumstances, and vary in different persons; and consequently the manifestations of mental disorder are various in the extreme. The central fact is the instability and inefficiency of the highest arrangements of the brain, and according as this insufficiently organised structure gives way here or there, to this extent or that, deliberately or rapidly, the result is manifested in this form of madness or in that, in epilepsy, in ungovernable passion, in hysteria, in paroxysmal drunkenness, in obsession, in imperative idea, in agoraphobia or claustrophobia, or in some other mental malady. I do not think that any one of these is heritable *per se*, but every one of them is an indication of that instability of the highest nervous arrangements which is heritable, though it is by no means necessarily inherited. That is the position. The children of those who suffer from any one of these disorders are liable to suffer either from that or from some other manifestation of the instability. They will not necessarily suffer, but they will be liable to suffer; and if there are several children they may perhaps all of them suffer, and it is very unlikely that they will all escape, but they will suffer in different degrees and from different manifestations. I do not know that any one manifestation of the diathesis is more indicative of heritability than any other, but if there is one such it is undoubtedly epilepsy. The epileptic parent not only is very apt to transmit the general diathesis of instability, but he is, I think, peculiarly apt to transmit his own particular form of it.

Scope of Legislation Restricting Marriage.

No doubt under any rigorous system of eugenics, persons who exhibit this diathesis by any of its signs would be prohibited from marriage; and although I am no advocate of the legislative restriction of marriage, I must say that I should oppose but half-heartedly a law to prevent the marriage of epileptics; but farther than this, as at present advised, I should not go. In some cases these persons inflict upon their offspring, who are apt to be numerous, a very heritage of woe; but it must never be forgotten that it is to these very families that many men of very exceptional ability owe their origin. I have given what I think is the reason for this in another place, and need not pursue it here, but I believe there is good reason to think that Dryden was expressing a fact of inheritance when he said—

> Great wits to madness sure are near allied,
> And thin partitions do their bounds divide.

ABSTRACT OF

The Bradshaw Lecture

ON

HYSTERIA IN SOME OF ITS PROSPECTS.

Delivered at the Royal College of Physicians of London on Nov. 4th, 1913,

By T. R. GLYNN, M.D. Lond., F.R.C.P. Lond.,
PROFESSOR OF MEDICINE, UNIVERSITY OF LIVERPOOL; CONSULTING PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL.

In discussing the hypotheses advanced to explain the nature of hysteria, Professor Glynn was of opinion that the ingenious theory of Breuer and Freud of the effect of latent mental trauma on the mind claimed respectful attention, but their contention that this subconscious shock is always of a sexual character was repellent and cannot be accepted without further investigation. Janet's theory of a restricted field of consciousness explained a number of hysterical symptoms, but failed to account for others which were physical—such as of disturbance in the circulation, and the nutritional and trophic disorders that were occasionally met with in the disease. He referred to the case of a girl with hysterical paralysis who suddenly and painlessly lost all her nails, to another girl who in a similar condition in one night lost most of her hair, to two cases of erythematous eruption, to cases of hysterical œdema and muscular atrophy.

He alluded to Charcot's stigmata and to the precautions to be exercised in examining patients suspected of being hysterical. He had found tremor of the closed eyelids in 80 per cent. of these subjects. Dyschromatopsia, as well as restriction of the visual fields, was exceedingly common, but the field for red was not invariably the most extensive; monocular diplopia and macropsia were pretty frequently met with. In a few instances the common sensibility of the lining membrane of the nose was impaired, as strong ammonia held under the nose caused no discomfort.

In men, said the lecturer, the fragmentary hysterical paroxysms—transient giddiness, dimness of sight, and confusion—were as valuable as indications of hysteria as were the more pronounced fits in women; he had found a history of such attacks in four-fifths of men suffering from traumatic hysteria. The plantar reflexes were not only absent in hysterical paraplegias, but very frequently in other cases of this disease. In examining the subjects of the so-called "nervous shock," with symptoms so often of an entirely subjective nature, the greatest assistance was afforded by conducting the investigation according to Charcot's method. In this way hysterical and neurasthenic cases were readily differentiated. Out of 160 cases of nervous shock, 112 were suffering from hysteria or hysteria combined with neurasthenia, and 48 from simple neurasthenia.

The presence of Charcot's stigmata pointed to the existence of a hysterical condition, but did not indicate that the actual symptoms were necessarily dependent on the disorder. In certain subjects any affection may give rise to, and be attended with, hysteria, and some affections, organic and functional, show a particular proneness to occur in association with the disease, by reason of some predisposition common to both—age, sex, and constitution. In many instances the presence of the functional disorder may not add to any difficulty of diagnosis, but in its recognition an explanation may be found of certain symptoms, obscure pains and sleeplessness, and the diagnosis be rendered more complete. In other cases the presence of a complicating hysteria may lead to error. Illustrations were given of mistakes in diagnosis arising under these circumstances.

The lecturer then considered hysteria as he had met with it in association with epilepsy, chorea, chlorosis, Graves's disease, stomach disorders, diseases of the heart and nervous system. He had found the stigmata of hysteria present in

about 20 per cent. of epileptics, and in the majority of these there were more salient symptoms of the disorder. In four instances the epileptic attack towards its termination presented all the features of an hysterical crisis. In eight cases the epileptic and hysterical fits in the same individual occurred independently. In the majority of the other cases—12—besides the stigmata pointing to hysteria were such symptoms as neuralgic pains, headaches not connected with fits, palpitation, sleeplessness, vivid dreams, tremor, and pain over the heart.

Certain of the hysterical stigmata were found in 25 out of 96 cases of Sydenham's chorea, and in many some more pronounced features of the disease were also present. Together with the incoördinate movements of chorea, there were such manifestations as rhythmical spasm of an arm, rhythmical twitching of the eyelids, regular clonic movements of the legs, and rigidity of the legs. In one case hysterical rhythmical spasm followed chorea after an interval of two days, and in another in the course of two months. In two other instances the chorea was not of the ordinary type, and seemed to be a hysterical or subconscious renewal of former attacks of genuine chorea. In the remainder of the 25 cases there were such symptoms as neuralgic pains and tender spots in 10, vomiting without apparent cause in 2, aphonia in 2, semi-hysterical attacks in 4, typical hysterical cough in 1. To emphasise the distinction between ordinary and the so-called hysterical chorea several tracings were exhibited of rhythmical tremor and spasm.

The infective diseases, continued Professor Glynn, may provoke hysteria, and the affection may complicate their progress as well as follow during convalescence. Cases of rheumatic fever and typhoid associated with hysteria were referred to. Chlorosis for obvious reasons was, he said, very frequently attended with hysteria. Out of 164 cases of chlorosis, 45, or 25 per cent., were hysterical. In 20 out of the 45 there was much headache, as a rule vertical, with restlessness at night and vivid dreaming. Eighteen suffered more or less from obstinate vomiting and gastralgia, 5 had hysterical fits in some form, 8 exhibited fine tremor of the hands, 4 complained of pain and tenderness over some part of the spine, and 3 of great weakness of the legs. Two developed hysterical anorexia.

In Graves's disease the hysterical stigmata were present in 35 per cent.

There was evidence of hysteria in the presence of the stigmata and in a few of other symptoms, in three-fourths of the cases of simple gastralgia in young women. It was not likely that the hysteria was only accidentally associated with the gastralgia, since they were found together in so many instances; moreover, the hyperæsthesias and pains are just as characteristic a feature of hysteria as are the anæsthesias.

He had met with 15 cases of anorexia nervosa, and in each of these certain hysterical stigmata were present. One subject of the disease became comatose and was measured for her coffin, but under vigorous treatment recovered. Two died, one was removed to a nursing home when hopelessly weak and the other recovered for a while but in 12 months relapsed and died. Another case was very exceptional, the subject of the disorder being a boy.

The hysterical stigmata were present in 23 per cent. of the cases of gastric ulcer in young women, that is in patients with a history of hæmatemesis or melæna.

The relation of hysteria to heart disease was of special interest. Such hysterical affections as pseudo-angina, or simple pain over the heart, palpitation, dyspnœa, and syncope, when the heart is normal arouse fears of cardiac disease in the patient, and worry the medical attendant till he lights on the explanation of the symptoms, and when these hysterical accidents occur in cases where there are signs of organic heart disease they are likely to cause the patient's condition to appear more serious than it is. Further, as nervousness, sleeplessness, and pain are usually associated with hysteria the symptoms due to heart disease tend to be aggravated. Several cases were referred to in illustration. One was a girl with mitral stenosis who after a faint lost the power of her left arm; the paralysis proved to be hysterical in nature and not due to cerebral embolism.

In conclusion, Professor Glynn discussed the alliance between hysteria and the functional and organic diseases of the nervous system.

ON THE STATE OF THE BLOOD-VESSELS IN SHOCK.

BY JOHN D. MALCOLM, F.R.C.S. EDIN.,
SENIOR SURGEON TO THE SAMARITAN FREE HOSPITAL, LONDON.

IN 1893 I published [1] my belief that in cases of fever, of post-operative intestinal obstruction, and of traumatic shock there is a contraction of the arteries extending from the arterioles to the larger vessels and progressing until the causal conditions are removed or the patient is moribund. That view was opposed to the teaching of the day that the vessels of the splanchnic area become paralysed in the state of shock and it has also been urged from time to time [2] against the theory that the vessels throughout the body become relaxed. This last theory has for the past six or eight years been almost universally accepted, but recently its accuracy has been less assured, and at the Seventeenth International Congress of Medicine, in the debate on the Pathology of Shock,[3] not one speaker suggested that the arteries are relaxed or dilated in that condition.

The time, therefore, seems opportune for a review of the evidence on this subject, and I propose to state again very shortly the chief points in the argument in favour of the contention that the arteries contract as shock develops, and to indicate some of the more recent facts which have been brought forward in relation to this question. I give precedence to the clinical evidence because it constitutes my justification for offering an opinion and because the value of laboratory work to the surgeon must in the long run be judged by its success in explaining clinical conditions.

Clinical Considerations.

When in the course of an operation a patient passes into the state of shock, even if he loses little or no blood directly from divided structures, his tissues become obviously more and more bloodless, and careful observation during operations upon the abdomen shows that the anæmia is as conspicuous in the splanchnic area as in any other. This observation has been confirmed by Dr. G. W. Crile [4] who wrote concerning his laboratory work that both before and after death from shock "the arteries were quite empty, the tissues pale." He also said that when the splanchnic area was not involved in the manipulations of an experiment "autopsies did not reveal a condition of vascular distension in this area different from that of other areas." [5] Unless these observations are altogether mistaken, it is certain that there is no dilatation of the vessels generally or of those in the splanchnic area alone in the state of shock.

During the progress of severe operations it may occasionally be observed that the arteries become imperceptible at the wrist whilst the pulse-rate is not quickened or even is slower, and the beats of the carotid are full and bounding. On one occasion it was noted that at the end of an operation upon a healthy young woman the pulse-rate was 48 to the minute, and no pulsation was perceptible in any vessel of the extremities. The operation, an ovariotomy, was not a severe one, and the usual state of the vessels was restored after a very short time. A similar combination of signs was frequently observed passing gradually back to the normal or developing into the rapid heart action which is characteristic of well-marked cases of shock.

Such conditions could only arise from an increased opposition to the flow of blood through the small vessels and a well-sustained output of blood from the heart. The dissociation for a time of the small, weak, or imperceptible pulse from the hastening of the heart beats which usually accompanies it suggested that the arterial contraction was the more constant change. It did not seem possible that in some cases the arteries could be contracted whilst in others they were relaxed, or that in the particular cases now under discussion the active contraction which certainly

[1] The Physiology of Death from Traumatic Fever, J. and A. Churchill; also THE LANCET, Feb. 25th (p. 408) and March 4th (p. 460), and 11th (p. 519), 1893.
[2] THE LANCET, August 26th (p. 573), 1905; Brit. Med. Jour., Dec. 9th, 1905; Transactions of the Royal Medical and Chirurgical Society, vol. xc., p. 563; Transactions of the Medical Society of London, 1909.
[3] Section III., General Pathology and Pathological Anatomy, August 11th, 1913; THE LANCET, Sept. 16th, 1913, p. 726.

[5] Loc. cit., p. 139.

occurred could become a relaxation without some sign of the gradual or sudden change. If the change was gradual the pulse at the wrist would come back to its ordinary volume if only for a short time, a condition never observed during the development of shock. If contraction of the vessels suddenly became relaxation there would certainly be some acute disturbance which could not be overlooked clinically. As there were no signs of any such changes, there could be no doubt that the contracted vessels did not relax.

All authorities agree that the heart is stimulated to greater effort as shock develops and there seemed to me to be much reason for believing that the slow heart action associated with a small or imperceptible peripheral pulse might be observed more readily, if not only, in cases in which the heart muscle was relatively strong. When these observations were made the work at the Samaritan Free Hospital consisted in great part of the removal of large ovarian tumours, and it seems probable that such cases offered unusual opportunities for the observation of the effects of a comparatively powerful heart. It is well known that cardiac hypertrophy is a physiological effect of gestation, and it is reasonable to suppose that the presence of an ovarian tumour would at least occasionally induce a similar change. This view was supported by the fact that in a few cases an opportunity was obtained of examining the heart at a necropsy when its action had for a time remained slow after the pulse at the wrist became very small or imperceptible, and in these cases the cardiac muscle was always well developed, whilst in one instance there was a very obvious cardiac hypertrophy without any gross cardiac or renal lesion or other discovered cause of this condition except the presence of the tumour. The facts recorded led me to assert in 1893 that "if the heart be sufficiently strong its action remains slow,"[6] but that if still greater contraction of the vessels takes place the heart becomes relatively feeble and its pace quickens.

The extreme pallor in all the tissues, the definite evidence that in some cases the arteries were tensely contracted whilst the heart action was not hastened, the known fact that stimulation of the sensory nerves causes arterial contraction, and many other observations which cannot be set down in a short paper, were considered together to form a proof that "in traumatic fever, in shock and in abdominal distension following a laparotomy, the small feeble pulse, whether slow or fast, is in no sense due to cardiac weakness, is not a condition beginning at the heart, but is an immediate effect of the contraction of the vessels."[7]

If these contentions were true it was certain that the total volume of blood in the arteries must diminish, and in the absence of any marked venous distension it was argued that the fluid parts of the blood must escape from the vessels into the tissues. In cases of intestinal obstruction after abdominal operations, in which also it was held that the vascular capacity steadily diminished, there was no doubt that a great loss of fluid from the body did occur, because this condition is characterised by an extreme degree of exudation of fluid into the intestine and out of the body by vomiting. Moreover, in this condition the vomited fluid is at first clear, and gradually becomes yellow, green, brown, and nearly black. These changes indicate that not only fluid escapes from the vessels but that there is also an excessive and increasing destruction of blood cells in the liver. In the state of shock there is little time for such obvious indications of blood destruction to show themselves, and it does not follow that an excessive secretion of bile of short duration will be ejected from the stomach through the œsophagus, but sometimes recovery from shock is accompanied by vomiting of bilious or even black fluid, and the amount of fluid lost from the skin is always great when the condition is well marked.

The loss of fluid and other constituents of the blood from the vessels was regarded as the cause of the extreme anæmia of the whole body, and death was attributed to a starvation of the various tissues and organs which might be traced in the evidences of the failure of their functions. When the vaso-motor centres were affected the whole body died.

Experimental Considerations.

A short *résumé* of the experimental evidence shows that it is conclusive in support of the clinical. The theory that in shock the animal bleeds into its own splanchnic veins has now no supporters. Dr. G. W. Crile's first book advocating the view that shock is characterised by a general vascular relaxation was published in 1899,[8] and in that year also Romberg and Pässler[9] advanced the same view on very much the same grounds with regard to the conditions found in toxæmic fevers. In regard to both shock and toxæmic fevers it was argued that death was not due to cardiac failure, as was then generally believed, but that there arose a loss of tone in the vaso-motor system followed by a failure of the circulation when the vessels relaxed. This view had a great vogue as regards shock until quite recently. Romberg and Pässler's communication did not apparently attract so much attention.

The argument depended entirely upon the interpretation of the fall of blood pressure. It has long been known that a stimulation of sensory nerves excites reflexly a general arterial contraction and a consequent rise of blood pressure in the large arteries. Conversely a relaxation of the vessels lowers blood pressure in the large arteries. It was shown in 1899 that if the stimulations of tissue were sufficiently severe or if fever was sufficiently continuous the blood pressure after a rise fell very low, and this was regarded as a proof that arterial relaxation had occurred. It was argued that the fall of the pressure became so great that when the state of shock was fully established the vessels were completely relaxed, and this condition was attributed to a paralysis of the vaso-motor centres from over-stimulation and consequent exhaustion of their energy. But this argument omitted altogether the possibility that the volume of blood in the vascular system might diminish and the obvious fact that the tissues became anæmic both in shock and in fever. As Yandell Henderson has pointed out, the conclusion that the vessels relaxed was arrived at because the authors of this view "applied to their problem that conception of the circulation which the physiology of to-day teaches. This was their sole mistake."[10] Many new facts were demonstrated by detailed records of most interesting experimental work, and none of these facts have been contradicted in any material respect, but the evidence is now very strong that the interpretation was at fault. As early as 1903 physiologists began to question the evidence that the vaso-motor centres become paralysed. In that year Professor W. T. Porter and Dr. W. C. Quinby, of the Harvard Medical School, published experiments showing that in the state of shock the vessels were still influenced reflexly by nerve stimulations, and they concluded that "exhaustion of the vaso-constrictor nerves cannot therefore be the essential cause of the symptoms termed 'shock.'"[11]

In 1907 Professor Porter recorded another "investigation into the effect of uniform stimulations of the depressor brachial and sciatic nerves at various levels of blood pressure from the normal down to about 9 mm."[12] of mercury. He showed that "the absolute change in blood pressure upon stimulating these afferent nerves remains almost unchanged until the blood pressure has fallen to about one-third its usual height,[13] and that "the reflex fails only when the blood pressure sinks to a level at which anæmia of the vaso-motor centres is certain. Indeed, all we know regarding these and similar cells strengthens the belief that their endurance under stimulation is very great. On the other hand, they are extraordinarily sensitive to changes in the blood-supply." It was added that "the data presented are wholly opposed to the hypothesis that would explain surgical shock by the exhaustion of the vaso-motor centres."[14]

The question of the state of the vessels in shock was also studied by Dr. M. G. Seelig and Professor E. P. Lyon, of Saint Louis, Mo., U.S.A.,[15] who performed an ingenious experiment upon a series of dogs showing that division of the sciatic nerve made a greater proportional increase of the blood flow from the previously divided femoral vein in a shocked animal than the increase observed in the other leg of the same animal before the state of shock was brought about. The deduction was drawn that "this proportional difference must

be referred to the fact that in the shocked animal, before division of the sciatic the vessels are in a state of greater contraction than they are in the normal animal." The authors of these observations invited Dr. John Green, jun., to examine the eyes of dogs before and after the induction of shock, and to note carefully the size of the vessels of the fundus without telling him what was or was not expected. "In every instance he reported that the vessels showed a marked degree of contraction after the animal was in shock." Sometimes the vessels resembled mere threads, and in one case the contraction was observed immediately before the animal died.

Dr. Eugene Boise holds that the chief cause of the fall of blood pressure in shock is an abnormal increase in cardiac contraction and a decrease of cardiac relaxation by which the capacity of the heart becomes so reduced that it cannot adequately fulfil its propelling functions. From an analysis of Crile's records and from his own investigations Boise argued that in shock "there is an excessive irritation of both the vascular and cardiac centres whereby the arteries and heart are both almost spasmodically contracted."[16]

Professor Yandell Henderson, of Yale University, U.S.A., has formulated a very large conception regarding the effects of diminution of the quantity of CO_2 in the tissues. His views are in many respects altogether original, and they seem to me to throw a flood of light upon conditions about which we have hitherto been quite in the dark. Haldane and Priestley had confirmed[17] the observation of Miescher that variations in the amount of CO_2 in the body are very important and had shown that very slight differences of the pressure of this gas in the pulmonary alveoli (normally about 5·5 per cent. of an atmosphere) lead to an immediate hastening or slowing of the respiration until the normal tension is readjusted.

Mosso had demonstrated[18] that under reduced atmospheric pressure the CO_2 content of the blood is diminished and that this diminution is one of the causes of the disturbance of function in mountain sickness. He suggested the term acapnia (α, privative, and καπνός, smoke) for this diminished pressure of CO_2.

Following up these indications Henderson worked out his scheme and he has summarised his views thus.[19]

> From the data to be presented in this series[20] of papers it appears that the CO_2 content of the blood exercises regulating influences upon the heart rate, upon vascular tonus, upon the peristalsis of the alimentary canal, upon the mental condition and upon a number of other functions of the body to a degree so far as we can find from the literature, hitherto in great part not demonstrated. These data show that even a slight reduction in the CO_2 content of the arterial blood causes a marked quickening of the heart rate. Further reduction induces an extreme tachycardia, complete cessation of peristalsis, failure of many reflexes and coma. If an extreme reduction of the CO_2 content of the blood is effected very rapidly the heart comes into a state bordering on tetanus. This cardiac tetanus practically abolishes the pumping action of the heart, arterial pressure falls therefore, and death results.
>
> If the reduction in the arterial CO_2 is less extreme, but is maintained for a considerable time (an hour or more according to the extent of the reduction), so that the tension of CO_2 in the venous blood and in the tissues is greatly reduced, symptoms and conditions result which are similar in many respects to those occurring in mountain sickness and apparently identical with those of shock.

Henderson says that "acute acapnia diminishes the volume of the blood as effectively as does an extensive hæmorrhage,"[21] and that "arterial pressure ultimately sinks in spite of an intense activity (not because of failure) in the vaso-motor nervous system, and in spite of an extreme constriction (not because of relaxation) of the arterioles."[22]

The influence of a subnormal amount of CO_2 in the tissues has been investigated also by Dr. E. Jerusalem and Professor E. H. Starling of University College, London, who state that their experiments[23] confirm Yandell Henderson "in his description of the action of the heart when the CO_2 of the blood is reduced to very low limits."

Thus from many independent sources there is an overwhelming mass of experimental evidence, and much more could be quoted, to the effect that the heart and the vessels are both stimulated to increased activity as the state of traumatic shock develops.

But Yandell Henderson's scheme involves a much wider area than the vascular changes in shock. He says that acapnia has been found "in many forms of fever, in diabetic coma, in the conditions consequent on violent muscular exercise, and in that form of shock which results from the intravenous injection of albumose and 'peptone.' In all of these conditions, as well as in mountain sickness, excessive artificial respiration, and surgical shock, there occur at one stage or another, and in varying order, hyperpnœa followed by shallow respiration or apnœa, tachycardia, venous congestion, and fall of arterial pressure, muscular weakness, suppression of reflexes, disturbances of consciousness and disturbances of the motor functions of the alimentary canal."[24]

It is impossible in a short paper to attempt to give any adequate account of Yandell Henderson's teaching, but it seems to be in complete accord with my contention mentioned at the beginning of this paper, that in cases of fever, of post-operative intestinal obstruction, and of traumatic shock there is a persistent and increasing contraction of the arteries, a conclusion which I believe to be demonstrable at the bedside.

These very short remarks indicate with as little detail as possible the views of the state of the vessels in shock which seem to me to be supported by the clinical and experimental facts set forth. The matter is obviously of great importance, for if it is a mistake to believe that the vessels relax as a consequence of severe or continuous injuries it is hardly likely that much real progress can be made in the study of operative conditions until that mistake is rectified. The opposite view that the vessels contract offers a much more certain guide both for understanding and treating the conditions found. And as regards the detail that in fevers and in shock the same vascular changes take place, I am convinced that this fact, as I believe it to be, gives an immense advantage in understanding clinical phenomena to those who accept it.

FOURTH REPORT ON TYPHOID CARRIERS.

BY D. S. DAVIES, M.D. LOND., LL.D., D.P.H.,
MEDICAL OFFICER OF HEALTH OF BRISTOL;
AND
I. WALKER HALL, M.D. VICT.,
PROFESSOR OF PATHOLOGY, BRISTOL UNIVERSITY, AND PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY.

With the Assistance of G. SCOTT WILLIAMSON, L.R.C.P. & S. Edin., L.F.P.S. Glasg., *Pathologist to the Bristol General Hospital;* and B. A. I. PETERS, B.A., M.D., D.P.H. Cantab., *Resident Medical Officer, Ham Green Hospital, Bristol.*

IN the last report[1] it was concluded that the results then obtained justified a prolonged study of the case in hand. The present note deals with the further course of the condition.

The methods employed are the same as were detailed in former communications. For reasons previously stated the examinations have been limited to the search for typhoid bacilli in the excreta, the determination of the agglutinin contents of the serum, and the action of therapeutic agents.

The carrier was a female, aged 33, who had enteric fever in July, 1905. Since that date eight cases of infection had been traced to her. She came under observation in January, 1909, and proved to be a urinary carrier. For a period of three months urotropine was given continuously. The excretion of typhoid organisms in the urine was decreased but not inhibited entirely. On April 21st, 1909, a bacillary emulsion prepared from the patient's own organism was given. The doses were continued until 1000 millions were reached. The injections were discontinued on Sept. 29th,

[1] THE LANCET, Sept. 3rd, 1910. See also Journal of Pathology and Bacteriology, 1910, vol. xv., p. 120; THE LANCET, 1908, vol. ii., p. 1585; and Proceedings of the Royal Society of Medicine, 1908, Epidemiological Section, p. 175.

1909. From October, 1909, to January, 1910, typhoid bacilli were not excreted in the urine. On Jan. 4th they reappeared and persisted until Feb. 27th. During this period the agglutination reactions varied from 1 : 1000 to 1 : 1800. Potassium citrate was given for three weeks. There was a cessation of the bacillary excretion until the following July.

Fourth Report.

The observations now recorded show that the urine of this patient has remained free from typhoid bacilli for two years. We feel justified in recommending the discharge of the patient from hospital, subject to her promise to report herself should any of her former symptoms reappear, or for additional treatment if current experimental investigations upon the adjuvant action of drugs or metals upon typhoid bacilli prove worthy of trial in similar conditions.

On Nov. 1st, 1910, the patient was removed from the Ham Green fever hospital to the Bristol Royal Infirmary and placed under the care of Dr. J. A. Nixon. Her temperature was normal and her general systemic condition good. On the 7th a cystoscopic examination was made by Mr. C. F. Walters. He states:—

> The bladder was found to be normal except at the right ureteric orifice, the lips of which were markedly œdematous and superficially ulcerated. Above the right ureter there was an area of trabeculation. Catheterisation of the right ureter was difficult owing to the œdema. The catheter could be introduced about 1½ inches only: here there was an impassable obstruction.

The urine obtained from the right ureter contained much pus and yielded a pure growth of typhoid bacilli. The left ureter was catheterised with ease, and the urine was free from pus and typhoid bacilli. A skiagram was taken; it showed a shadow in the region of the right kidney. On the 21st Mr. Walters explored the right kidney. To the naked eye it did not show any abscesses, cysts, or contractions. When bisected longitudinally during a search for foci of suppuration ten small calculi were found lying in one mass near the pelvis. The calculi were removed, the cavity was scraped, and the kidney sutured and returned into the body. The renal cavity yielded a pure growth of typhoid bacilli. Typhoid bacilli were isolated from the calculi also. The calculi were composed of phosphates and organic material only. At noon on the next day the temperature commenced to rise, reached its highest point (104·2° F.) on the 24th, and then fell gradually, reaching the normal on Dec. 1st. A slight effusion appeared at the right base. Recovery was uneventful. During this period the agglutinins reached and remained at 1:1500. On the day following the operation bacillus typhosus was grown from 5 c.c. of blood obtained in the usual way. Pus and typhoid bacilli were found in the urine during the first four days after the operation, the agglutination reaction being positive, 1 : 1000. During the following fortnight the typhoid organisms disappeared from the urine, and the agglutination fell to 1 : 250. Pus and bacilli then reappeared and persisted for the next eight months.

Comparing the clinical features of the case at the time with those of Rousing,[2] Greaves[3] and Adrian, and Meyer and Ahreimer,[4] the condition was less advanced, as there was not any definite pyonephrosis, nor were there any signs of a marked renal involvement, such as acute localised pain or difficulties with micturition. At the operation the renal pelvis did not appear to be affected. However, the changes in the right ureter were of long standing, so that the pelvic mucosa most probably shared in the ureteral focus. The bladder remained free from superficial changes.

The rise of temperature subsequent to the operation and the concomitant appearance of typhoid bacilli in the blood stream, as well as in the later increase in the agglutinin content, suggest that a mild septicæmic condition was brought about by the disturbance of the focus. The chart on next page indicates that the organisms were rapidly overcome. We have not obtained any evidence as to the occurrence of any other focal lesion following this invasion. Had the immunity been low or the organisms of exalted virulence such a result might have been produced.

Course of Borovertin.—Onwards from the operation the typhoid organisms and pus were present in the urine. On

* G. S. W. is responsible for October, 1910, the whole of 1911, and for Jan. 2, 3, 4, 17, 18, March 7, 8, June 16, 17, 1912. I. W. H. is responsible for the remainder and for the blood determinations. B. A. I. P. made all the clinical observations while the patient was at Ham Green fever hospital.

Temperature chart for the days following operation.

March 4th, 1911, therefore, it was decided to give the patient one drachm of borovertin daily. This was continued until May 24th, when it was stopped, because the patient complained of being "run down." During this period of administration of the borovertin she lost 7 lb. in weight. When the drug was discontinued recovery to her usual condition was rapid. On July 31st she had regained her average weight. Borovertin was then recommenced and given in the same doses until Sept. 2nd. The weight again fell 5 lb. During these courses of borovertin the excretion of bacilli was unaltered. On reference to Table I. it will be seen that pus and bacilli were present in the urine throughout.

Course of specially prepared Bacterial Emulsion.—On July 1st, 1911, the blood yielded a typhoid organism which was agglutinated by the patient's own blood in 1:500, and after three weeks' cultivation 1 : 800. Cultures of this organism and of a subculture from the urine were repeatedly subcultured for three weeks on (1) serum agar, (2) blood agar prepared with the patient's own blood, and (3) carbolic acid agar (1:10,000 gradually increasing to 1:500). At the end of the three weeks a bacterial emulsion was prepared from a mixture of the growths on the several media and injected.

Table I. shows that the urine ceased to contain pus and typhoid bacilli during October, 1911, while the agglutinating power of the blood rose to 1/2500. The systematic examinations carried out since then until July 23rd, 1913, have failed

TABLE II.—*Injections of Bacterial Emulsion.*

Date.	—	Remarks.
1911.		
Sept. 2nd.	25,000,000	—

,, 4th.	100,000,000	—
,, 5th.	400,000,000	—
,, 6th.	800,000,000	Giddiness and malaise were complained of. There was also slight pyrexia.
,, 23rd.	1,600,000,000	—
,, 27th.	3,200,000,000	—
Oct. 1st.	6,400,000,000	Giddiness and sickness. Pyrexia. Compelled to remain in bed for three days.

to reveal any further excretions of the organisms, while the agglutination titre has fallen to 1/150.

Blood cultures.—The blood has been examined during the periods of bacillary excretion. On four occasions it has been found sterile; twice it has yielded a strain of bacillus typhosus which was agglutinated 1:500 by the patient's own serum, the agglutination reaching 1:800 after repeated subcultures during three weeks.

Inhibitory power of urine.[5]—Table III. shows the inhibiting power of the patient's urine upon various micro-organisms. The effect was not obtained when the urine was boiled before being added to the emulsions. Exposure of the urine to strong sunlight did not alter the inhibitory power. Normal and carrier urines were filtered through a Chamberland candle. 0·1 c.c. of urine and 0·1 c.c. of an emulsion containing 10 millions of B. coli, B. typhosus (the various strains being denoted by the letters A, B, C) or staphylococci, were incubated for 1–2 hours, and then shaken and sown upon lactose litmus agar plates. After 48 hours at 37° C. the resultant colonies were counted.

TABLE III.—*Showing the Inhibitory Power of the Urine upon Various Micro-Organisms.*

Date.	Urine quantity.	Normal urine, number of colonies per plate.	Carrier's urine, number of colonies per plate.	Bacterial strains.
1911.				
May 2nd.	0·1 c.c.	64	3	B. coli A.
		34	0	B. coli B.
		111	13	B. coli C.
		34	41	Staphylococci.
		108	0	B. typhosus A.
		77	15	B. typhosus B.
		210	34	B. typhosus C.
August 17th.	0·1 c.c.	100	6	B. coli.
		32	0	B. typhosus.
		19	33	Staphylococci.

On the above dates typhoid bacilli were not found in the urine. The carrier urine did not inhibit the growth of staphylococci, but exerted a marked effect upon the typhoid-coli group.

The evidence of tissue reaction.—The agglutinin content of the blood has been determined at intervals and in periods of about four days each. The method followed was that adopted with the object of obtaining comparative results.[6] Table I. shows the high content at the time of the operation and the slow but gradual fall since the cessation of the special vaccine injections. There is still, however, a considerable agglutinative power. Whether this is due to a "habit," or arises from the stimulation of some latent focus, time alone can tell.

Condition of the bladder and ureter in September, 1913.—On Sept. 23rd a further cystoscopic examination was made by Mr. Walters. "The bladder," he says, "was found to be normal in appearance, no trabeculation was visible, and all signs of inflammation had disappeared from the right ureteric orifice."

This patient has now been under our continuous observation for four and a half years. Like other carriers of the urinary type, she has exhibited "intermittent" periods. These have varied from a few days to a few weeks. One of them, however, extended to eight months (April, 1909, to January, 1910). Since August, 1911, we have not been able to demonstrate the presence of typhoid organisms in the urine. The routine practice during this time has been to centrifugalise 15 c.c. of urine and to use the whole of the deposit for enrichment methods prior to plating out. The quantity has been increased to 100–200 c.c. whenever the microscopical appearances of the deposit were at all suspicious. Throughout the whole course of the case bacillus coli has been present occasionally. Sometimes these organisms were associated with a small amount of pus: more frequently there

[5] These experiments were carried out by G. S. W.

[6] THE LANCET, Sept. 3rd, 1910, p. 723.

was not any evidence of reaction. For six months the latter condition has prevailed.

It is perhaps well to state clearly that we do not claim that the typhoid latency has entirely disappeared. The agglutination reactions, in the light of earlier appearances, do not permit of such a contention. Still, the comparatively sudden cessation of the bacillary excretion, the concomitant rise in the tissue reaction, and the subsequent freedom from symptoms, &c., lead us to hope that such a result may be possible. We intend to continue to make periodical examinations of the urine and to apply further medication when called for.

The observations now recorded have been made possible by the action of the Public Health Committee of the Bristol Corporation in allowing the carrier to remain at the Ham Green fever hospital and by several grants towards the expenses of the laboratory investigations from the Bristol University Colston Society's Research Fund. The patient herself has displayed a willing and intelligent coöperation throughout.

DISEASES DUE TO DEFICIENCIES IN DIET.[1]

BY F. GOWLAND HOPKINS, M.A. CANTAB., M.B., D.SC. LOND., F.R.S.,

FELLOW OF TRINITY COLLEGE, AND HONORARY FELLOW OF EMMANUEL COLLEGE, CAMBRIDGE.

THE whole trend of modern pathology has made our minds ill prepared to believe in an extraneous deficiency as the prime cause of a specific disease. We recognise perforce inherent deficiencies in the body of structure or material; but even these, when they are not anatomical and obvious, we tend to look upon as for the most part only predisposing or contributory; the essential and immediate cause of any disease we rather seek in the intrusion of some positive factor, some *res noxia*, be it parasite or poison. So completely is this course justified in general that there is doubtless an excuse for the present tendency to seek for such an intruder in cases where there would seem to be little reason to expect its presence, as in certain diseases of nutrition.

When disease is ascribed to diet the implication is nearly always that the food is infected or poisonous, or at any rate that some constituent is in such excess as to be deleterious. Some malific factor of a positive sort is usually thought to be essential. Even the pioneer in the work upon beri-beri, although his labours had given him the essential facts, did not escape the effect of what seems a bias. Eykman proved that the symptoms of beri-beri followed upon the eating of polished rice and showed that the addition of the missing pericarp was curative; but he was constrained to hold, not the simple, and apparently obvious, view that the pericarp contained something necessary for normal metabolism, but that toxins developed in the endosperm, while a constituent of the pericarp was able to neutralise them.

It is rather remarkable that neither physiologist nor pathologist rendered ready belief to the suggestion that among the dietetic needs of the animal might be organic substances small in amount and easily overlooked by the chemist. The suggestion had been in the literature of nutrition experiments for many years, but it was neglected. Yet since the animal has always been adjusted to live directly or indirectly upon plant tissues, which contain countless substances other than proteins, carbohydrates, and fats, there was no *a priori* reason to doubt that physiological evolution might have made some of these substances essential. Yet had the fact been definitely established in the nutrition laboratory it might have seemed wholly of academic interest. It might well have been doubted that any important deficiency in such substances could occur in practical dietaries. It required such facts as those which have come to light in connexion with beri-beri to establish a wide and practical interest in the matter. The case of beri-beri is, indeed, a very remarkable one. The wide consumption by whole races of a one-sided dietary, the localisation of a specific substance in a grain, an artificial treatment of that grain exactly adjusted to remove the substance, and the occurrence of prominent symptoms as a result of its removal—all these coincidences were necessary to yield so striking a proof that a disease may arise from a dietetic deficiency. Without them it is unlikely that we should have been engaged in this discussion.

Many of us believe that the establishment of this plain case may lead us to discover many others less obvious, and that a new chapter in the subject of animal nutrition is now opening. It is only to be hoped that those who help to write the new chapter will display due caution. The whole literature concerning the relations of food to health and disease is so flooded with baseless theories, with fads and fancies, that it is well to see that no new channel shall be opened to them.

I take it that to obtain satisfactory evidence that a specific diet deficiency is directly responsible for a given complex of symptoms it must be shown that the association between the suspected diet and the symptoms is sufficiently frequent, and the occurrence of the symptoms upon normal diet sufficiently rare, to satisfy the statistician; while to obtain rigid proof we must discover what the deficiency really is, and prove that removing it results in prevention or cure of the symptoms.

In defining our criteria I think it is justifiable to insist upon the fact that the disease need not be wholly absent from individuals using normal diets, but only sufficiently rare. What is absent from a faulty dietary may be the necessary raw material for some particular metabolic process, or some hormone which initiates the process. In such a case all individuals consuming the dietary must sooner or later suffer from whatever is involved in the failure of that process. But it is clear that in an occasional individual assimilation may be faulty; the apparatus in which the process occurs may develop faults, or other factors necessary to its continuance may fail. The final result will then resemble that due to the absence of the raw material. Our criterion must be this: that the disease is absent from, or rare in, individuals taking a normal dietary, but common among those who are rigidly confined to the diet under suspicion. When individuals escape, the evidence that they have added nothing of significance to their diet is difficult to obtain, for all that we know at present about the subject suggests that very small additions may make all the difference to the results. But any considerable degree of individual immunity would be evidence that the etiology of the disease involves some positive factor and not a deficiency alone. In the case of beri-beri and in that of scurvy we have evidence which very nearly, if not entirely, satisfies such criteria. There is scarcely any doubt that they are diseases due to deficiencies of diet and to those alone. The same cannot perhaps be said of any other specific disease.

It is clear that in opening this discussion I can deal only very briefly with individual instances.

Concerning beri-beri, I would like first to say that after reading all the descriptions I could find of cases which are supposed to have occurred under normal dietetic conditions I feel—without pretending to be an expert in matters of diagnosis—that the evidence they offer against the modern view is unimportant. It is to be hoped that the question of its cogency will be discussed.

The present position of the beri-beri question is of particular interest because, owing to the brilliant work of Casimir Funk, we have considerable knowledge concerning the nature of the substance of which the deficiency is responsible for the disease. We have not final knowledge, as Funk will probably be the first to admit. I will venture to say that I myself am more impressed with the objective proof he has given us that the phenomena before us depend upon tangible substances than by the evidence he offers for the actual constitution of what he has so appropriately termed vitamines.

In the case of scurvy the probability that a diet deficiency is an essential etiological factor has, of course, been long forced upon the attention. The remarkable thing is that the probable deficiency should have been so long discussed in terms of known substances. It was so easy to prove that none of those suggested—potassium salts, citric acid, and the like—had anything to do with the matter, and it was always clear that a substance so unstable and so easily lost

[1] Remarks introductory to a discussion in the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on Oct. 21st, 1913.

from normal foodstuffs had to be looked for amid the unknown.

The work of Holst and his colleagues upon experimental scurvy, though it has not told us what antiscorbutic substances may be, has thrown much light upon their essential properties. Anyone who lacks conviction can easily learn how great may be the effect of small deficiencies in diet by repeating the observations of Holst and Fröhlich under rigid experimental conditions.

When we consider in particular acute infantile scurvy we find what seems to be the clearest evidence for the influence of a deficiency produced by the artificial treatment of milk, combined with much conflict of evidence as to the degree and kind of treatment which is capable of inducing the deficiency. This is a well-worn question, but there is some justification for saying a word or two about it. In discussing it I must refer again to the work of Holst and Fröhlich.

It should be noted first of all that the symptoms and post-mortem appearances exhibited by animals such as guinea-pigs after some weeks of a grain dietary are most strikingly similar, even in their details, to those found in Barlow's disease. Any one who has troubled to repeat the observations will hardly doubt that the etiology of the two conditions must be essentially the same. The main symptoms may develop in guinea-pigs in advance of any loss of weight, while, when similar animals are fed upon fresh vegetables the symptoms remain absent, even if the diet be insufficient and weight is rapidly lost. The condition is clearly no result of general malnutrition. After it is established giving fresh vegetables or vegetable juices gradually removes the symptoms, but if heated, dried, or long kept such materials lose there curative power. What is especially interesting in connexion with the point I am dealing with is the fact that in different foodstuffs the antiscorbutic substance exhibits varying degrees of stability, which may suggest either that it is not always the same or that varying conditions affect its stability. Fresh milk was shown by Fröhlich to have a definite antiscorbutic influence in guinea-pigs. Milk, in fact, contains both a substance inhibiting the induction of beri-beri symptoms and another which is antiscorbutic. They are not the same, as Funk has pointed out, since their stability towards heat is markedly different.

Now, it would seem from the results got in experimental scurvy that the temperature at which the antiscorbutic substances in milk are destroyed can be sharply defined, for Fröhlich found that after heating to 70° C. the milk used by him retained its preventive power, whereas ten minutes' exposure at 98° completely removed it. It is remarkable, therefore, that there should be such uncertainty concerning the effect of milk sterilisation in the case of infantile scurvy. One point is obvious. When data are collected clinically uncertainty as to the precise dietetic history of individual cases must always be considerable, and it is sure that even the occasional consumption of antiscorbutic substances in small amounts makes a great difference in the result. But we may perhaps find, as Funk suggests, a more important factor of uncertainty in the varying qualities of the milk-supply itself. There are a great number of circumstances which induce variations in the ordinary known constituents of milk, and Funk has produced evidence to show that the vitamine related to beri-beri may vary in amount. It occurs to one that such a special substance as an antiscorbutic might well tend to fail toward the end of a long lactation. Mixed milk-supplies must vary much in the proportion they contain of early lactation and late lactation products as well as varying in other ways. It is not at all impossible that one type of milk may, for one reason or another, withstand, in respect of its antiscorbutic power, more severe treatment than another.

I have dwelt a little upon this familiar subject for two reasons. First, because it illustrates certain difficulties inherent in the study of deficiency diseases; and secondly, because it seems to me that recently acquired facts suggest that, in spite of all that has been done, there is yet room for further investigations concerning the relation between milk sterilisation and infantile scurvy; investigations which must be made under conditions more carefully standardised than before. The same may be said with regard to rickets. Even those who are convinced that rickets takes origin from a dietetic deficiency have to admit that it is difficult to find a common factor among the dietaries held to be responsible for the condition. But now that we know how small in amount and how unstable in character certain essentials of food may be, our inquiries into the dietetic history of patients should become more detailed than before, and carried out perhaps with more faith in their bearings.

I should like to touch next upon pellagra, but time permits only the briefest reference. It once seemed probable that this disease might prove to be due to a diet deficiency quite different in nature from those we have hitherto considered. Maize is deficient in the aromatic amino-acid tryptophane, and a certain minimum supply of tryptophane is undoubtedly necessary to life. It would have been interesting to learn that a specific disease might arise from lack of an amino-acid, and long ago, having shared in the discovery of tryptophane, I took a special interest in the etiology of pellagra, and performed a good many inconclusive, and therefore unpublished, feeding experiments. Dr. F. M. Sandwith has lately referred again to the possibility of this deficiency playing its part. But the recent demonstration, so largely due to Dr. L. W. Sambon, that pellagra occurs with some frequency in this country, and in individuals who have certainly not relied upon Indian corn as a basal diet, seems to put the suggestion out of court, as well as the view, much more widely held, that the disease is due to infected maize. If Dr. Sambon is right as to its probable frequency in this country the remark I made earlier with regard to the possibility of deficiency diseases sometimes occurring upon a normal diet can have no bearing here, and we shall have to admit that pellagra is not related to diet.

I propose to close with a brief reference to experiments of my own which relate to the effect of diet deficiencies upon growth. They have no very real relation to the present discussion, and I have already on more than one occasion made their results public. But I quote them now because they offer further conclusive proof that the removal of substances, minute in amount and of unknown nature, can produce an extraordinarily marked effect upon the physiological properties of a dietary. Upon a diet consisting of purified materials (one essential in the process of purification being thorough extraction with alcohol) young rats absolutely cease to grow, even when their consumption of food is quantitatively normal. On the other hand, if what is removed by alcohol be returned, or if very minute amounts of milk or fresh tissue extracts be added, the animals grow quite normally on the same basal dietary. I quote the results with special confidence now, because during a prolonged endeavour to discover the nature of the substances concerned, an endeavour which has continued until now, I have accumulated a great amount of experimental material. On the properly prepared diet not one rat out of many scores has ever continued to grow for more than a few days. Rats are so little prone to scurvy or to anything resembling the symptoms of beri-beri that they serve especially well to demonstrate this growth failure in a pure form.

Being in possession of a diet which, while supporting the animal for considerable periods, does not permit of growth, one was naturally tempted to try its effect upon the rate of development of cancer. Owing to the kindness of Dr. E. F. Bashford in supplying me with material I was first able some 18 months ago to make observations upon a strain of Jensen's rat sarcoma. All the rats to be used for the experiment were injected at the same time with a standard dose of tumour and fed for a few days upon a normal diet. They were then divided, without any selection, into two groups. One group was fed upon bread and milk, the other upon the purified artificial dietary. Otherwise the conditions were precisely the same. At a given period all the animals were simultaneously killed and their tumours dissected and weighed. Thirty-two rats upon bread and milk showed an average tumour weight of 14·5 grm.; 28 rats upon the artificial dietary gave an average weight of 3·9 grm. In the absence from diet of the substances which promote the growth of normal tissue the sarcoma grew at only one-fourth of its normal rate. Such a result has perhaps no more than an academic importance, but it shows that a neoplasm, like a normal tissue, requires for its growth certain at present unknown substances, which it acquires less readily from the tissues than from the food-supply of its host.

Cambridge.

SENSITISED VIRUS VACCINATION IN GONORRHŒA, AND ESPECIALLY ITS COMPLICATIONS.

BY LOUIS CRUVEILHIER, M.D.

THE method of sensitised virus vaccinations devised in 1902 by Professor Besredka [1] was first applied by me [2] to the treatment of gonorrhœa, and especially of its complications. We tried the method in several cases of prostatitis, and the complications of gonorrhœa which we systematically treated by this method were epididymitis, metro-salpingitis, and gonorrhœal rheumatism.

We thought it would be specially interesting to use Besredka's sensitised virus vaccination method for the treatment of *epididymitis*, which of all complications resulting from gonorrhœa is undoubtedly the most frequent. Most of the patients we have treated had been sent to us by our teacher, Dr. Castaigne, and our friends, Dr. Fouquet and Dr. Partuier. All our patients promised to use no other treatment; we advised them, however, to wear a well-made suspensory bandage.

In one case the pain was so acute as to cause the patient to faint, and in other cases the pain radiated towards the heart, the thigh, the loins, the gluteal region or the abdomen, yet it was very soon influenced by the treatment, so that most of our patients who complained of sleeplessness slept well on the very night following the injection. However acute the pain may have been in all the cases which came under our notice it usually disappeared within 12 hours after the first injection, sometimes after 24 hours, and we never observed it 48 hours after beginning the treatment, so that on the next day our patients experienced no more difficulty in standing or walking. In this way some of them were able to resume their work, and one of our patients, who delivered articles at houses, had to interrupt his work during 35 hours only.

The symptoms of local inflammation, such as redness, heat, and tension of the skin over the testicle, decreased and then disappeared together with the pain. In four cases after the second injection only, but more usually after the third—i.e., from five to eight days after commencing the treatment—we noticed the entire disappearance of tenderness on palpation of the epididymis. This organ recovered its normal sensitiveness as well as its usual suppleness and size. As a rule, however, we noticed the persistence of a painless nodule occupying the end of the epididymis. In one case a nodule was still perceptible three weeks, and in another case one month, after commencing the treatment.

In all our patients, none of whom was under the necessity of remaining in bed, all being able to come to our laboratory every morning to be examined or treated, we had the satisfaction of seeing that the various general symptoms usually accompanying epididymitis disappeared within a short time. As our patients were able to sleep and had ceased to suffer their appetite returned, and after two or three days' treatment they no longer presented the sickly, thin, and depressed aspect habitual to patients suffering from gonorrhœa and epididymitis. The fever usually accompanying every inflammatory process in the region of the epididymis disappeared in the course of 24 hours after beginning treatment. Each of our patients had two or three injections administered at intervals of 48 hours. We have not a single relapse to report amongst the various cases which came to our notice.

We have tried the method of sensitised virus vaccination in the treatment of *utero-annexal complications* resulting from gonorrhœa, which so frequently necessitate serious surgical operations. In all the cases examined the results obtained were very good. Usually the very first injection brought about a considerable change for the better and lessened the discharge; after the second, and sometimes after the third, injection the abdomen recovered its suppleness and ceased to be painful on palpation, so that the patients could wear corsets again. The general health soon became excellent, and on examination of the uterus it was found entirely free from congestion, the annexa were supple, and there was only a slight glairy oozing in which it was not possible to discover the presence of the gonococcus. In cases of metro-salpingitis with effusion into the tube the satisfactory result of the method was not less evident, and a fortnight or three weeks after beginning the treatment the swelling noticed at the site of the tube disappeared, and usually only a very slight local sensibility was noticeable at the point of the insertion of the tube into the uterus. The method of sensitised virus vaccination appears to act even in cases of metro-salpingitis of long standing, and we obtained a complete cessation of all painful symptoms as well as of the discharge in the case of a woman whose infection dated from the time of her marriage nine years previously.

We thought it reasonable to try sensitised virus vaccination in *acute gonorrhœal rheumatism*. In cases of gonorrhœal rheumatism with acute pain which we had to treat the action of virus vaccination was very rapid; after four or five injections the patients usually desired to stop the treatment, as they no longer felt any pain or inconvenience on movement. In the case of patients who consented to return a fortnight or a month after the last injection in order to be examined by us we never found that any painful symptoms had reappeared.

In cases of gonorrhœal rheumatism taking the form of hydrarthrosis on the day following the first injection the patients expressed a manifest abatement of pain. After five or six injections a careful examination showed that the joint had become perfectly painless. The patient could bend his joint quite normally and execute every movement with perfect ease.

The form of acute arthritis is certainly the most common form of gonorrhœal rheumatism; now in every case we treated the results obtained were very good. This was specially so in the case of a patient who had been sent to us by Dr. Ravaut, and whom we treated with the assistance of Dr. Marato.

The patient last March became aware of a urethral discharge, as well as very painful symptoms of sciatica which soon obliged him to stay in bed. Notwithstanding the administration of aspirin, salophen, phenacetin, and valerian cachets, in spite of the application of sinapisms and blisters, and of frequently repeated spraying with chloride of ethyl, and of massage with various liniments, and especially with the "balm of Bengué," the patient suffered greatly; he neither relished nor digested his food, and could not sleep although morphine injections were frequently administered. The illness made such rapid progress that by April 15th the whole length of the spine was painful; in the loins the patient felt such distressing shooting pains that he was forced to lie motionless on his back. In vain was it tried to give some relief by means of enemas with salicylate and afterwards with antipyrin, by vibratory massage, by cupping, hot-air applications, and by injecting under the skin of the abdomen blood drawn from the arm. By May 10th the right ankle and knee were attacked also.

On June 11th the first sensitised virus vaccination was done, and at the same time every other drug and local application were given up by the patient. Soon after the injection the pain in the spine had considerably abated. On the 13th a second injection was given, followed by a somewhat violent reaction, which, however, brought about a considerable diminution of the painful symptoms, so that it was possible for the patient, for the first time since the beginning of his illness, to get up without help. On the 17th a third injection was given, after which the pain in the ankle and knee completely disappeared. On the 20th a fourth injection was given. From that time he only felt a dull pain in the upper part of the spine; he could sit up, lie down, stand up, and remain standing without help. The nights became excellent; he began to go up and down stairs; but the injections were continued at three days' interval till the end of the month.

In the opinion of all medical men *chronic gonorrhœal rheumatism* is particularly refractory to all treatment, so that it has been said that "its real treatment must above all be preventive, consisting in the treatment of gonococcic arthritis during its acute stage in order to prevent it becoming chronic." Now we thought that the method of sensitised virus vaccination might be of great use in this form of disease. It was found so in the following case.

The patient, who was sent to us by Professor Dopter, had for more than a year been suffering from pains in the joints of the right foot, knee, hip, and elbow, whilst on the left side the pain was in the heel, the knee, and the wrist. The pain, which was acute and became worse on the slightest movement, particularly on walking, had not been influenced by electric treatment, massage, wrapping the parts in cotton wool, doses of salicylate, nor by the various changes of climate tried by the patient. The pain remained localised in the lower part of the left heel, above the ankle-bone and behind the sheath of the tendons, as well as in the right heel and metatarsal bone joints, so that walking had become an absolute impossibility. Though not very high the temperature was slightly above the normal.

[2] Louis Cruveilhier: Comptes Rendus de la Société de Biologie, Jan. 4th, April 19th, June 28th, July 5th and 12th, 1913; Berliner Klinische Wochenschrift, August 11th, 1901.

On April 29th Professor Dopter asked us to apply our method and we gave the first injection. On the next day the patient felt decidedly better. Further injections were given on May 1st, 6th, 8th, 12th, and 14th. A considerable diminution of the painful symptoms, in the heel especially, was noted. The injections were repeated on the 16th, 21st, and 24th. Though not entirely cured the patient was considerably better, and on June 2nd the pain was no longer perceptible except in two toes of the right foot. The lameness is better and walking is becoming more and more easy, so that a complete recovery can be expected after a few more injections.

Finally, we have had quite recently the opportunity of treating four patients who had suffered for four, five, nine, and ten years respectively from pains in the joints which seemed to be refractory to all the medicines, such as salicylate and aspirin, usually employed against rheumatism. As these patients had formerly suffered from gonorrhœa, we thought it advisable to try the method of sensitised virus vaccination, and after two, three, and four injections we had the satisfaction of noticing either a considerable change for the better or an entire disappearance of the articular pains.

Experiences of this kind have led us to think that a large number of arthritic diseases, attributed to rheumatism, belong to the domain of gonococcic infection, and that in all cases of rheumatism where the usual treatment does not give any results, and especially when a gonococcic origin can be surmised or traced, it is well to have recourse to sensitised antigonococcic virus vaccination.

The action of Besredka's sensitised virus vaccination has been more especially observed by us in the course of complications resulting from gonorrhœal infection, but it is nevertheless true that we have obtained very good results in the treatment of *acute* and even *chronic urethritis*.

In cases of acute urethritis where our help was sought we always obtained most encouraging results. The pains and local inflammation disappeared in most cases after the second injection, and at the same time the discharge grew less abundant, and also very rapidly lost its yellowish-green colour and its thickness, and took the aspect and fluidity of soapy water. The time of its disappearance was different in various cases, but after an interval of four weeks its disappearance was usually complete. None of the cases we treated showed any complication whatever.

Chronic urethritis appeared to us to be as beneficially influenced by our method of sensitised virus vaccination as the acute form of this disease. From the very first injection we always noticed a rapid decrease of secretion as well as a notable change in its appearance, for it soon became transparent like glycerine. All other disorders imputable to former prostatic infections, such as a feeling of heaviness near the anus, perineal pains, as well as pain in the region of the sacrum, usually disappeared after the first injection.

Remarks.—We have not yet come to any final conclusions concerning the various modifications which, in our opinion, ought to be made in Besredka's method of sensitised virus vaccination in order to adapt it to the treatment of gonorrhœa. Yet we are able to state that, as has been proved by the experiments of Metchnikoff and Besredka[3] in antityphoid vaccination, it is always preferable to inject living sensitised virus. In a certain number of cases, when we had absolutely failed whilst persisting in using dead sensitised virus, we obtained excellent results from the use of living sensitised virus. The serum which we employed in our operations was taken from a she-goat to which we had successfully applied Besredka's subintrant injections of the veins in order to render it immune.[4] We considered that it was not advisable to take from the patient himself the gonococci to be sensitised, and we took them from the cultures which we had had in stock for several months, and several samples of which were obtained by the kindness of Messrs. Maras and Forgeaud. Our injections were principally made in the subcutaneous cellular tissue and were repeated at intervals varying according to the different cases. None of the patients who had recourse to our help showed any sign of severe general reaction. In some cases there was a slight rise of temperature during the hours which followed the injection. Sometimes we also noticed at the site of the injection some erythema accompanied by a pain which never lasted longer than 48 hours.

Paris.

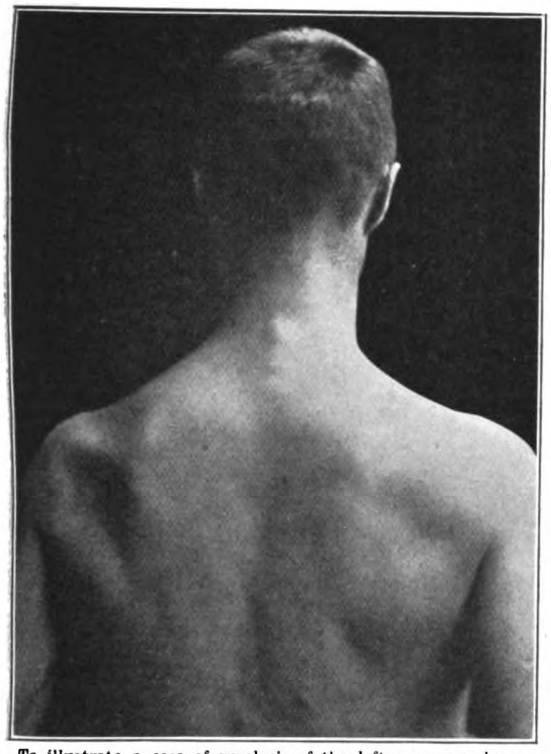
SOME ADDITIONAL EXPERIENCES OF NERVE SURGERY.

BY A. H. TUBBY, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE WESTMINSTER AND THE ROYAL NATIONAL ORTHOPÆDIC HOSPITALS, ETC.

A CONTRIBUTION on "Nerve Surgery" was made by me to the Sixteenth International Medical Congress, held in Budapest, and was published in THE LANCET of Sept. 4th, 1909, p. 706. An opportunity is now taken of tracing the further progress of the cases then referred to, and of adding new ones.

The operation for facial paralysis by facio-hypoglossal anastomosis has proved to be a permanent and almost complete success. The patient was shown at the Royal Society of Medicine in 1909, and it was then difficult to distinguish which side of the face had been affected, except for the fact that there was, in repose, a very slight droop of the left angle of the mouth. All the movements on that side of the face were perfect, there was a total absence of associated movements of the tongue and face, and the tongue was protruded directly and without any deviation.

Of the cases of operation on the brachial plexus[1] one was for Erb's or the upper arm type of infantile paralysis, where the anterior branch of the fifth cervical nerve was grafted into the sixth, with gradual recovery of power in the biceps and partial recovery in the deltoid,[2] the fibres to these muscles on the outer and upper part of the fifth nerve cord being split off and inserted into the sixth nerve cord. Improvement took place in the deltoid in so far that three years after the operation the arm could be abducted 8 inches from the side, when the scapula was held. A better result would have been obtained if the significance of a paralytic subluxation of the shoulder had been recognised and the looseness of the capsule rectified as a preliminary step.



A case of severe laceration of the brachial plexus and complete paralysis of the right arm was also reported upon.[3] Here there was absolute and complete paralysis of the whole of the muscular and sensory area supplied by the brachial plexus. All the nerve roots were found to have been torn apart, and were matted together by fibrous tissue; scar tissue also intervened between the proximal and distal segments of the nerves. The scar tissue was excised and the proximal and distal segments of the plexus were sutured together *en masse*. Five years afterwards—that is, in March, 1911—the recovery of motor power had extended to the biceps, brachialis anticus, and the deltoid. The patient could flex the forearm fully and abduct the upper arm to a right angle, sensation had returned over the distribution of the upper external cutaneous branch of the musculo-spiral nerve and over the internal cutaneous branch of that nerve, and recovery is still slowly progressing.

Neuroplasty on the popliteal nerves, after anterior poliomyelitis, has not been by any means so successful, and an explanation may be found in Warrington and Murray's hypothesis[4]—viz., that, "there may be sufficient nerve cells left to supply one group of muscles, but insufficient to supply two"; or, to put it in another way, there are enough cells to supply the internal popliteal nerve, but not the external as well, and *vice versâ*. In one case where the distal part of the external popliteal nerve was grafted into the internal no result followed, perhaps due to the fact that there was also some degeneration in the internal trunk, or that the remaining nerve cells were insufficient.[5]

In a second case, one of paralytic equino-varus, where the distal part of the external popliteal was grafted into the internal popliteal nerve, no sign of recovery was observed during two years, and then the area of the previous operation was exposed. It was then found that the grafted portion of the external popliteal nerve was evidently undergoing regeneration, as shown by the increasing size of its distal part as compared with the free proximal part, and by its whiteness, roundness, and firmness. It was further noted that direct stimulation of the distal or grafted portion of

the external popliteal nerve caused contraction of the anterior and external leg muscles. Here the outlook may be described as distinctly hopeful.

One example of talipes calcaneus, where the nerves to the soleus and gastrocnemius were separated from the internal popliteal trunk and grafted into the external, showed partial recovery during a term of three years, but the condition has been stationary for the next three years; that is, whilst the patient has recovered sufficient voluntary power to plantar-flex the foot when it is off the ground, yet when seen in July, 1913, the improvement in muscular strength had been arrested. And a similar remark may be made of another case of talipes calcaneus where the range of ankle movements became almost normal, without, however, there being sufficient strength to lift the weight of the body on the toes of the affected foot alone. Such is the record up to date of cases of nerve-anastomosis and neuroplasty reported previously.

We must now pass on to more recent cases.

CASE 1. *Traumatic lesion of the brachial plexus; operation; nearly complete recovery.*—A male was admitted to Westminster Hospital on Sept. 9th, 1909, with a history that 12 months ago he had been knocked down by a heavy wagon. He stated that his shoulder had been dislocated and the dislocation had been reduced, but he was unable to use his arm. On admission it was noted that whilst movements from the elbow downwards were good, with the exception of full power of extension of the fingers, there was a partial loss of voluntary movement at the shoulder-joint. Sensation was present below the elbow, but dull in places. Electrically, it was found that the biceps reacted, but there was no response of the supra- and infra-spinatus, deltoid, triceps, extensor carpi radialis longior and brevior, and of the extensors of the wrist. He was operated on on Jan. 24th, 1910, and the brachial plexus was exposed. There was found to be marked thinning of the fifth and sixth cervical nerve-cords just before they joined the seventh, and the fifth and sixth cords were surrounded by fibrous tissue. This was dissected away and the thinned cords were enveloped in Cargile membrane. Recovery set in rapidly and the affected muscles began to regain power, except the extensors of the wrist, where recovery has been much delayed.

CASE 2. *Injury of the suprascapular branch of the brachial plexus; operation and recovery.*—A male, aged 30 years, was brought to me by my friend Mr. A. Scott-Turner on May 13th, 1910. Ten months before this, in August, 1909, he was yachting, and one night the boat was rolling very heavily. In the morning he woke up with pains in his shoulder. He was aware of having hurt it in the night, and he thought it possible he might have struck his shoulder against the side of the bunk. The pain continued for three weeks, and he noticed he could not raise his arm so well as before. The loss of power increased and he consulted Mr. Scott-Turner. When the patient came to see me the arm hung by the side, and it could not be held up for long without support. External rotation was limited, and there were two deep hollows (Figs. 1 and 2) above and below the spine of the scapula, evidently due to the wasting of the supra- and infra-spinatus. The posterior fold of the axilla was less full than normal, and on testing these muscles electrically there was no reaction to galvanism or faradism with any bearable current. It was evident that the suprascapular nerve was involved, but it was impossible to say if it was torn, if it had merely been stretched, or if it was embedded in cicatricial tissue. An exploratory operation was therefore done on May 31st with the assistance of Mr. E. R. Carling and Mr. H. F. Strickland, Mr. Scott-Turner giving the anæsthetic.

A triangular flap was turned up over the subclavian triangle with the apex towards the point of the shoulder. The omo-hyoid was situated very low down, and crossed the triangle immediately above the clavicle. Search for the suprascapular nerve proved long and tedious, as it was abnormal in its origin and course. It was found that a nerve-trunk came from the outer side of the plexus. On testing with sterilised electrodes we ascertained that this cord was composed of the outer head of the median and possibly of the suprascapular. To verify this anatomically the clavicle was sawn across and the cord traced downwards. Opposite the lower border of the clavicle a branch of the cord above mentioned was discovered, which on being traced backwards to the upper border of the scapula was evidently the nerve we were in quest of. About half an inch from the spot where this nerve separated from the outer head of the median it was seen to be embedded in cicatricial tissue. Electrical stimulation above this point gave a very feeble reaction in the supra- and infra-spinatus, whereas stimulation below gave a full reaction. The cause of the paralysis was therefore evident. The scar tissue was dissected away, and a piece of subcutaneous fat was freed so as to form a flap, which was fixed around the site of compression of the nerve. It appeared to us that the abnormal course of the nerve threw light on the injury, and we thought that it must have been compressed during sleep, as the patient had rolled to and fro in his bunk. Another hypothesis was that his shoulder was wrenched and hæmorrhage took place, but the fact was that there was no bruising seen after the accident. Three weeks after the operation it was thought that the fossæ were beginning to fill, but no voluntary movement was present in the muscles. On July 14th, six weeks after the operation, there was definite reaction to galvanism in the muscles. Although the supra- and infra-spinous fossæ were still flat, yet the upper one had begun to fill up. Six months afterwards the fossæ had almost filled, and the patient could raise his arm to the full and hold it there. He could also rotate the arm well externally, and the power has gradually increased until now, when it is nearly as good as on the other side. This case was shown at the Congress, and the condition three years afterwards is shown in Figs. 3 and 4.

Four Cases of Injury of the Ulnar Nerve and of its Branches.

CASE 3. *Divided ulnar nerve in the middle of the forearm; operation; recovery.*—A woman, aged 48, was admitted to Westminster Hospital on Jan. 17th, 1908. Two months previously she had cut the middle of the inner border of the forearm with a glass bottle. The flexor sublimis digitorum was found completely divided, and the profundus was much lacerated. No lesion of the nerve was discovered at the time, and the ulnar artery appeared to have escaped injury. The wound was sewn up and the arm put up on a splint. When the wound was healed and the splint removed, complete paralysis below of the ulnar nerve was discovered. Reaction of degeneration was present in the interossei muscles and in the hypothenar eminence.

An operation was performed on Jan. 27th—i.e., ten weeks after the injury. The ulnar nerve was found severed, with half an inch of fibrous tissue between the ends, both of which were bulbous, the upper being much clubbed. Both ends were deviated from their track and turned outwards. Each end was freed, and the sections of the nerves brought together and sutured with catgut. The junction was refreshed and surrounded by Cargile membrane. On Feb. 7th—i.e., ten days after the operation—it was noticed that the ulnar side of the ring finger was sensitive to touch and pain, and when the little finger was pricked sensation was referred to the ring finger. With massage and faradism she afterwards regained complete sensation and good movement. The first dorsal and other interossei muscles were acting normally, although the hypothenar and the first dorsal prominence were not so marked as in the other hand. Gradually the affected hand became quite useful.

CASE. 4. *Ulnar nerve injury at the wrist; division of the superficial branch and bulbous condition of the main branch; operation; partial recovery.*—A woman, aged 21, was admitted to Westminster Hospital on Nov. 29th, 1909. On August 11th of that year she cut her left wrist with a bottle; the wound was stitched up, and when it was healed she noticed a loss of power in the fourth and fifth fingers. The hand was somewhat wasted, and the interosseous spaces on the back of the hand had begun to be hollow. On admission there was loss of sensation in the cutaneous distribution of the ulnar nerve, loss of power on separating the fingers, and abduction of the little finger. A puckered scar, 1½ in. long, ran obliquely upwards and inwards, from near the middle point of the front of the wrist to the ulnar border.

At the operation, within a few days of admission, the flexor carpi ulnaris was exposed and its ends turned aside. In a mass of scar tissue the superficial branch of the ulnar nerve was found, divided; and on the main trunk of the nerve there was a small bulb, but the continuity of the nerve was complete. The ends of the superficial branch were joined by catgut, and the thickening on the main trunk was freed from scar tissue and surrounded by Cargile membrane. On Oct. 10th, 1910, nearly a year after the operation and 15 months after the injury, sensation had returned to the fingers, except that touch was rather dull on the inner side of the little finger, which was still abducted. The muscles of the hypothenar and first dorsal interossei eminences were filling out. Electrical tests showed diminished reactions to faradism in the interossei muscles of the hand, but no polar changes to galvanism.

CASE 5. *Division of deep branch of the ulnar nerve; neuroplasty; partial recovery.*—A man aged 20, was admitted to Westminster Hospital on Oct. 3rd, 1912. On August 17th he had cut his wrist with broken glass. The wound was situated just above the pisiform bone, and was stitched up at once. On admission there was found to be loss of sensation both to pain and touch over the palm from the wrist to the base of the fifth finger, otherwise sensation was present. The interossei muscles, especially the first, were wasted. The patient could not separate the fingers with ease. On Dec. 7th the ulnar nerve and its branches at the wrist were dissected out, and in the scar tissue a bulbous enlargement on the deep branch of the nerve was found. The branch was twice its normal diameter at this spot. The bulb was excised, the ends sutured, and the junction protected by membrane. It was evident that the main trunk and its superficial branch had escaped. It was curious to note that the injury to the deep branch was situated 1 to 1½ in. distant from the deep scar on the skin, and was probably caused by the penetration of a pointed piece of glass. On Jan. 17th, 1913, it was noticed that there was no response to faradism in the interossei and there was a typical sluggish reaction to galvanism, whilst the lumbricales reacted to both currents. Since then the interossei have begun to respond slightly to both currents and the fingers are regaining strength and usefulness.

CASE 6. *Traumatic lesion of the deep branch of the ulnar nerve; nearly complete recovery.*—A boy, aged 12, was sent to me on Jan. 20th, 1910, on account of a partially clawed hand, following a wound on the inner side of the front of the wrist, at the end of August, 1909. The cut was a deep one and had detached the pisiform bone with the flexor carpi ulnaris attached to it, also one of the deep flexor tendons of the little finger and a fairly large nerve were severed. When I saw the boy this scar was more than 2½ inches long and extended to the middle of the palm inwards and upwards from the inner side of the base of the fifth finger. He had complete paralysis of the interossei. The fourth and fifth fingers were clawed, whilst the second and third were becoming so. Sensation in the fingers was defective. On the 31st a long and rather difficult dissection was made, and it was ascertained that the deep branch of the ulnar nerve was embedded in dense fibrous tissue at the base of the third metacarpal bone. The difficulties arose from the depth of the wound, from hæmorrhage from the deep palmar arch, and from the density and extent of the scar. The last was dissected out, the nerve completely freed, and its compressed portion wrapped in Cargile membrane. On Jan. 31st, 1911, it was noted that the fingers could be nearly straightened out voluntarily, the interosseous hollows were being filled up, the fingers would separate and approximate, and sensation to pain and touch were almost normal.

Deductions.

1. Brachial plexus lesions, if traumatic, are hopeful, if the loss of power has not existed for years. If due to other causes the outlook is not so good. However, we should not despair of a case recovering, even five years after the operation, provided that the improvement has set in within three months after the operation and is continuous.

2. Popliteal neuroplasty for infantile paralysis has proved disappointing for the reasons given previously.

3. Injuries about the wrist should never be sewn up until the continuity of the nerves has been ascertained, and until all the electrical reactions have been tested.

4. If the lesion of the nerve is compression by a scar the outlook after operation is most hopeful. If the nerve has

been severed primary operation is very hopeful, but secondary suture rarely permits a complete recovery.

5. No case, however, of traumatic nerve lesion should be regarded as hopeless, in view of the achievements of neuroplasty.

Finally, I should like to make a note on a painful condition connected with enlargement of the head of the first metatarsal bone, and I beg to refer to those cases where there is not only tenderness on the inner side of the joint, but also severe pain on its outer side and in the first interdigital space. This is a condition special to those cases where there is lipping of the joint surfaces and a deposit of osteophytes, and the cause appears to me to be as follows: On dissecting the part there will frequently be found a communicating branch passing from the digital trunk of the anterior tibial nerve to the corresponding nerve on the plantar surface. This communicating branch arises opposite the most prominent part of the head of the bone and passes immediately downwards over the capsule of the joint, to which in inflammatory cases it is often adherent, and it joins the digital branch of the internal plantar to the outer side of the great toe. It is easy to see how painful compression may arise, and the remedy I have adopted is simple—i.e., to dissect away the communicating branch and remove the osteophytes.

Harley-street, W.

PUBLIC MEASURES FOR THE PREVENTION OF TUBERCULOSIS.[1]

BY NATHAN RAW, M.D. DURH., F.R.C.S. EDIN., M.R.C.P. LOND.,

PHYSICIAN TO MILL-ROAD INFIRMARY, LIVERPOOL; MEMBER OF THE INTERNATIONAL COMMITTEE ON TUBERCULOSIS.

THE spread of tuberculosis in any community can only be efficiently and successfully checked by the adoption of public measures which will form a coördinated scheme for attack on the disease. Tuberculosis being to a large extent a disease of ignorance and misery, our efforts to prevent it must be directed towards the social conditions and insanitary surroundings of the poor. It is essential that a very close coöperation must be established between voluntary action and Government and municipal efforts in order that the spread of the disease can be controlled and proper means provided for the treatment and cure of those afflicted.

The general measures for the control of tuberculosis will be somewhat as follows: (1) Voluntary and compulsory notification; (2) removal of affected children from school and home; (3) treatment of children in special children's sanatoriums; (4) education of the general public with regard to the disease; (5) provision of municipal dispensaries in every community; (6) provision of sanatoriums for the cure of early cases; (7) institutions for advanced cases; (8) home training and supervision amongst the working classes; (9) rigorous supervision of the milk supply; (10) extermination of tuberculosis amongst cattle; (11) assistance to family in the absence of the breadwinner; and (12) provision of suitable employment to cured cases and those in whom the disease is arrested.

Voluntary and compulsory notification.—Tuberculosis being essentially an infectious disease it is desirable that a complete notification of all cases should be made to the officials who are responsible for the public health, so that they may be informed as accurately as possible of the existence of every person infected with the disease.

In England voluntary notification has been superseded by compulsory notification, at least so far as pulmonary tuberculosis is concerned, and although it is open to question whether or not it is desirable to notify the private patients of a medical man, yet if a certain amount of discretion is exercised there can be no doubt but that compulsory notification is in the general interest of the community, although it may press hardly on individual cases. A recent order from the Local Government Board, in London, compels the notification of every inmate of a public institution suffering from any form of tuberculosis. This notification must be made on special forms by the physician attending the case, and for which he receives a small fee of 1*s*. As soon as notification is received by the health officer a visit is made to the home of the patient, and a careful inquiry as to his personal condition and surroundings is made; if, in the opinion of the health officer, his home surroundings are such as to make it unsafe for him to remain power is given for the patient to be removed to some institution, but this power is very rarely exercised.

In large cities and habitations where a great amount of overcrowding exists, the treatment of the advanced case of tuberculosis is of supreme importance. If he is allowed to live in the same dwelling and share the same room as his wife and children, it will almost certainly happen that one or all of his family will become infected with the disease, and therefore it is absolutely necessary that he should be removed to some safer surroundings unless he is able to have a room to himself and to look after his own personal cleanliness. It is of no use to keep a patient in a sanatorium for six months and then discharge him as incurable, to spend the rest of his life in an overcrowded cottage where he may spread the infection to a new generation. Provision ought to be made, either by Govenment or by municipality, for the detention and comfortable treatment of all cases of incurable tuberculosis. I am not in favour of exercising compulsory powers of removal from a man's own home, but if it is for the protection of healthy people, then removal ought to be made compulsory; but I think it will be some time before public opinion is ripe for such measures.

The health authority will disinfect and clean the clothing and bedding of any notified case, and then will also carefully disinfect the house in which he has lived. Very often the patients complain of this attention to their homes and their clothing, but it is essential that it should be done for the protection of the future residents of the house. It is also the practice to notify to the health authorities any change of address of a tuberculous person, so that they may keep in touch with any house in which he may live.

On the whole, compulsory notification will prove useful in the fight against the disease, but it should only be used in a wise and gentle manner, as otherwise it is liable to cause personal discomfort and may have the effect of ostracising the patient from society. If it is pushed too far it may also have the effect of preventing him from earning his livelihood by reason of his fellow-workers having a fear of infection in the workshop or factory. Although many countries are still doubtful as to the wisdom of enforcing compulsory notification, yet from the point of view of suppression of an infectious disease it cannot be denied that with care and consideration the compulsory notification of tuberculosis is bound to do good.

Removal of affected children from school and home.—The medical inspection of school children is now thorough and complete in Great Britain, as in many other countries, with the result that a fair number of children of school age are recognised as suffering from pulmonary tuberculosis, although this number is not so large as one might be inclined to expect. Pulmonary tuberculosis is comparatively uncommon amongst school children, whilst the other forms of tuberculosis are more often seen. When a child is recognised as suffering from open tuberculosis it should at once be removed from school, mainly for the protection of the other children, as it is possible for one child in an overcrowded and badly ventilated schoolroom to infect several of its fellows. In the case of a family the infected child should invariably, if possible, be provided with separate accommodation, or, better still, removed from the family circle until recovery has taken place, but on no account should the child sleep with any other children or even with its parents.

Treatment of children in special children's sanatoriums.—The provision of special sanatoriums for children is, I am glad to say, in England making steady and rapid progress; many of these sanatoriums have been provided by the education authorities, with excellent results. It has been found undesirable for children to be treated in a sanatorium for adults; hence it is necessary to provide special institutions for them. The children's sanatorium has the double advantage of continuing the education of the child and at the same time providing the means of cure of the disease. In Germany, where the climate is more suitable for this treatment, a great many of such sanatoriums have been

[1] Being a report presented at the Eleventh International Anti-Tuberculosis Conference, Berlin, Oct. 22nd to 25th, 1913.

provided, and in Great Britain much success has attended their adoption.

Education of the general public with regard to the disease.—The main point in the campaign against tuberculosis must be in the education of the general public with regard to the disease. The National Association for the Prevention of Consumption aims almost entirely at this part of the work; it has numerous branches in most of the large cities and towns of the British Isles, where the work of education of the public is steadily pressed forward. A travelling exhibition, provided with models of everything necessary in the treatment of the disease, is constantly moving round from place to place, and demonstrations are given by competent teachers on the management and nursing of children, and the prevention of tuberculosis, in which popular lectures are given each evening by experts. In this way an enormous amount of information is steadily disseminated. Education of school children is constantly going on, and the teachers themselves are instructed in the methods of prevention and treatment of tuberculosis. Literature is scattered broadcast throughout the land, and illustrated posters are affixed in every town, so that every possible means is used to convey to the public the information so much required.

Provision of municipal dispensaries in every community.—The public dispensary has been proved to be of value in the treatment of poor persons afflicted with tuberculosis, and it is suggested that in every town the health authority should provide the municipal dispensaries where the poor may receive attention, and where the most careful inquiry can be made with regard to their families. The house of every infected person is carefully inspected and the accommodation noted. Advice as to nursing, isolation, and treatment is given in every case, and where necessary rigorous action is taken by the health inspectors. In this way it is hoped that every affected person may have the opportunity of receiving advice and treatment, together with assistance to his family if necessary. The National Insurance Act in England will quite revolutionise our present methods in dealing with tuberculosis. Every insured person is entitled to special treatment and if necessary to sanatorium benefit. In the case of anyone transferred to a sanatorium the dependents of the family will receive 10*s.* per week for six months, and if necessary further assistance will be given to the affected person. This is a great step in advance, and will undoubtedly induce a great many of the working class to accept treatment in a sanatorium, knowing that their family will be provided for in the meantime.

Provision of sanatoriums for the cure of early cases.—The provision of sanatoriums for treatment and cure is of vital necessity. Tuberculosis in its early stages responds admirably to sanatorium treatment, and it must be our aim in the future to obtain the cases at the earliest possible moment, so that they receive special treatment with a view to cure, and also receive special education and instruction with regard to their manner of living in the future. The sanatorium itself should be reserved for early cases of tuberculosis—it cannot be expected to do much good in advanced cases, and being of a very costly character its resources should be reserved for hopeful and curative patients. In the national insurance scheme such sanatoriums will be erected in every locality, and every suitable case will have the opportunity of cure. The results of sanatorium treatment have been excellent, and it is hoped that they will be still further improved as a better selection of patients is made.

Institutions for advanced cases.—In my opinion the most potent factor in the spread of tuberculosis is the advanced case who is not under proper supervision. The man in the final stages of consumption, who is pouring out millions of bacilli from his lungs each day and who has not physical strength to look after himself or take ordinary care, is a serious danger to the community. These are the people who require the most rigorous supervision and who as a rule are neglected by everybody. The late Professor Koch often said that he attributed the steady decrease in tuberculosis in England to the fact that such a large number of advanced cases of tuberculosis were isolated and treated in the Poor-law institutions of Great Britain; this statement is undoubtedly true, and the very fact that so many were constantly segregated must have had a great influence in the decline of consumption. Special institutions should be provided for advanced cases where they may be made comfortable and happy to the end, but it is doubtful if it would be wise at present to enforce isolation of such cases, although I have no doubt that in the future this will have to be done.

Home training and supervision amongst the working classes.—Tuberculosis being a disease of long standing it is necessary that those who suffer from it must be instructed in the manner of living at home. It is essential that the working man or working woman must attend to his daily duties, in many cases for years, whilst he is suffering from it; hence if he is to live at home with safety he must know how to protect the other members of his family. There is a strong prejudice in England against the working man using a sputum flask in the workshop or factory, so that there is every temptation for him to conceal the disease. It is not desirable, however, that a workman should be treated as a leper because he happens to be infected with tuberculosis, otherwise he is in danger of losing his ordinary place in the labour world and becoming a burden on the community. It is much more necessary that he should be instructed how to take care of his expectoration, and how to prevent the slightest tendency of infection to the healthy members of the community; and if this is done there is no reason whatever why he should not attend to his daily work and associate himself in ordinary social life. There is a great danger of frightening consumptives, and our efforts must be towards removing that fear and educating the general public in the right direction.

Rigorous supervision of the milk-supply.—The question of a pure milk-supply is of the first importance in every community, and of urgent importance as the staple food of infants and children. Notwithstanding what has been said by many experts in different countries there is no doubt whatever but that a large amount of tuberculosis is conveyed to children by means of infected milk and food. Tuberculosis is very common amongst dairy cows in Great Britain and Ireland—in fact, about 20 per cent. of cattle are infected with the disease at the present time. It is shown, however, that the cows with tuberculosis of the udder are by far the most dangerous, hence only about 2 per cent. of the infected cows are highly dangerous to children. It is the practice, however, in this country to mix all the milk from a herd of cows, so that one cow with disease of the udder may contaminate the whole milk-supply. Whilst consumption is steadily decreasing in this country the same cannot be said for tuberculosis in children. A very large number of the lesions occurring in children are the result of infection from tuberculous animals in the form of food, and every possible step must be taken to prevent such contamination of the food-supply.

Legislation has recently been introduced in England with a view of establishing a pure milk-supply, and it is proposed that all persons offering milk for sale should be registered and their premises periodically inspected. Every cow supplying milk will be under rigorous inspection by the health authorities, and compensation will be paid to the owner of any cow which is found to be suffering from tuberculosis. In the meantime the public are advised to sterilise the milk before being given to infants, with a view to destroying tubercle bacilli and other organisms. In Liverpool a great amount of special care has been taken by the health authority in safeguarding the milk-supply. Special powers have been obtained to inspect the source of all milk coming into the city, and the result has been that I have myself observed a steady decrease in hospital of children suffering from tuberculosis.

The amount of disease which is conveyed from animals to man seems to vary in different countries. In Scotland there is more than in England; whilst in the British Isles there appears to be more tuberculosis conveyed by milk than on the Continent, where it is almost the universal practice to pasteurise the milk before drinking. Whether this be so or not, we are all agreed that in the campaign against tuberculosis every effort must be made to eradicate the disease from dairy cows. This, I admit, is a very costly undertaking, and millions of pounds would be required to do it effectively in England alone. The scheme suggested by Bang, in Copenhagen, has had excellent results, and a similar process should be gradually introduced into every country.

Assistance to family in the absence of the bread-winner.—The question of providing assistance to the family in the absence of the bread-winner during his stay in sanatorium has been to a great extent solved by the provision in the National Insurance Act already referred to, but this work requires further extension, and a central fund ought to be

provided in every community for the special purpose of looking after the family when the parent is undergoing cure, otherwise it is impossible to expect him to give himself up for treatment for any prolonged time.

Provision of suitable employment in cured cases, and those in whom the disease is arrested.—The question of providing suitable employment for cured cases, and for those in whom disease is arrested, is one of great difficulty, although of immense importance. A very great many private employers are now giving such workers out-of-door, easy employment, as it is only in this way that they can be expected to remain well and fight the battle of life. We wish to extend such a practice in every country, and appeal confidently to those employers of labour who have the opportunity of making such provision for their workers.

By adopting a combination of measures such as those enumerated upon, we can confidently hope slowly but surely to exterminate the disease which ought not to be in our midst, but which is provoking such an amount of havoc, misery, and loss of human life.

Liverpool.

THE BACTERIOLOGICAL DIAGNOSIS OF A CASE OF PLAGUE.

BY W. J. TULLOCH, M.B., CH.B. ST. AND.

(From the Bacteriological Laboratory, College of Medicine, Newcastle-on-Tyne.)

THE following case is of interest in that it illustrates some of the many difficulties that exist in recognising cases of plague when they arrive at uninfected ports.

A boy 16 years of age, an apprentice on a grain ship that arrived in the Tyne from Rosario (River Plate), was taken ill on Sept. 10th, 1912. He was seen on the following day by Dr. W. E. Harker, medical officer of the Tyne port sanitary authority, who found him suffering from an indefinite febrile condition with high temperature, and it was noticed that he had a slightly enlarged and painful gland at the angle of the left jaw. In view of the fact that another apprentice had died at a continental port a few days previously from a condition which, as a result of post-mortem examination, was diagnosed as enteric fever, it was thought very likely that this boy had the same disease. The gland steadily subsided, but on the third day of illness signs of basal pneumonia appeared, and three days later the boy died, the cause of death at the time being uncertain.

At the post-mortem examination, made two days after the death of the patient, no gross pathological changes were noted beyond basal consolidation of the lungs, slight pleuritis, and some enlargement of the spleen.

Bacteriological examination.—At the first clinical examination material was taken for bacteriological investigation by puncturing the enlarged gland, and blood was obtained for carrying out an agglutination test with B. typhosus (Sept. 11th). The agglutination test was made at once, and it was found that the serum agglutinated B. typhosus in a dilution of 1/100 in one hour at 37° C. (The bacillus employed agglutinates with most typhoid sera in dilution of 1/100, while a certain number of sera agglutinate it in 1/500 dilution.) The material obtained from the gland—about 0·5 c.c. of fluid—was spread over the surface of three small agar tubes. After 48 hours' incubation at 37° C. four small colonies appeared. These consisted of organisms having the morphological and staining characteristics of B. pestis. Microscopical examination of the fluid had failed to show the presence of organisms.

The above findings indicated a further examination of the case by means of blood culture for the following reasons: (1) That the serum of the patient agglutinated B. typhosus fairly actively; (2) that the apprentice who had died at the continental port and who was said to have succumbed to enteric fever had only been ill five days; and (3) "a severe septicæmia may be present at a comparatively early stage of the disease"—plague (Indian Plague Commission).[1] It was important then in the present case to examine the blood by cultural methods—firstly, to exclude enteric fever, and secondly, in the event of the case being one of pneumonic or septicæmic plague, positive evidence of the nature of the infection would be rapidly and certainly obtained. Fifteen c.c. of blood were obtained by venipuncture of the median cephalic and run directly into 100 c.c. of broth. After 48 hours' incubation at 37° C. a few chains of Gram-negative polar-staining cocco-bacilli were noted in films made from the blood culture. By subculture on agar a plague-like growth was obtained.

The bacteriological examination of the organisms obtained from the gland and from the blood presented no difficulty. The growth on agar and other media and the biochemical reactions were typical of B. pestis, as also were the results of animal inoculation.

Three guinea-pigs were inoculated (rats could not be obtained at the moment). (*a*) One animal was inoculated in the flank subcutaneously with 3 c.mm. of an emulsion of a 24 hours agar culture suspended in 3 c.c. of saline. The animal died on the sixth day, and on post-mortem examination lesions typical of plague were noted—a mass of hæmorrhagic and necrotic tissue at the site of inoculation, injection and enlargement of the glands, and marked enlargement of the spleen, which was filled with hæmorrhagic and necrotic nodules. (*b*) A second animal inoculated with a similar quantity of the 48-hour blood culture died after two days, the examination revealing evidence of septicæmic infection—small hæmorrhages, particularly on the serous surfaces. (*c*) The third was inoculated by Bannerman's cutaneous method. The result was similar to (*a*) above.

A diagnosis of plague was made on the following grounds: (1) the microscopical and cultural characters of the bacillus obtained from the human material and from the lesions produced in the guinea-pigs; (2) the biochemical reactions of the organisms from both sources; (3) the control of the organisms recovered from the animals by culture on bile-salt media; and (4) cultural and histological examination of the lungs, liver, and spleen of the patient revealed the presence of B. pestis in these organs. In the lungs the organism could not be demonstrated in the alveoli, being found only in the capillaries, while the air spaces were filled with a polymorphonuclear exudate containing Gram-positive streptococci. The pneumonia was then apparently secondary and the case one of septicæmic, not of pneumonic, plague, and it seems probable that the gland condition was an early and slight involvement of the lymphatic system preceding septicæmic plague.

Criticism.—The result of the examination by blood culture shows, I think, that this method is one of which a more extensive use might with advantage be made, and one might go so far as to suggest that it would be well if it were employed in every case of febrile disturbance of indefinite nature occurring on ships coming from abroad. Especially is there danger of a wrong opinion being given on clinical grounds in cases of "pneumonia." "Pneumonia" occurring on ships arriving from ports where plague, epidemic or epizootic, is known to exist is potentially pneumonic plague, and before a diagnosis of pneumococcal pneumonia is made the former should certainly be excluded by bacteriological methods. Let us assume that this boy had been the first case of the disease to occur on board the ship, and let us suppose that he had been taken ill two or three days before the vessel arrived in the Tyne. The gland condition would have subsided, and a (clinical) diagnosis of pneumonia would have been justified by the symptoms and physical signs of the case. Again, considering the agglutination of B. typhosus by the serum of the patient along with the physical signs one might well have expressed the opinion that the case was one of ambulant enteric fever complicated by pneumonia. In such circumstances the true nature of the infection would not have been appreciated and the disease might have been widely disseminated. I state this hypothetical case to emphasise the importance of the information obtained from blood culture in making the diagnosis of indefinite febrile maladies occurring on board ship. As blood culture is a certain method of diagnosis in the septicæmic form of plague, and is a valuable aid to the diagnosis of other forms of the disease, this procedure should in my opinion be made a routine practice in the examination of such cases. Not only does it give definite information in a large number of cases of infection with B. pestis, but it will frequently serve to exclude infections with other organisms.

THE ESTIMATION AND SIGNIFICANCE OF AMINO-ACIDS IN THE URINE IN DIABETES MELLITUS.

BY P. J. CAMMIDGE, M.D. LOND.

IN 1894 Mies[1] reported the case of a little girl suffering from diabetes in whose urine an abundant deposit of tyrosine crystals occurred. Since that date Nicola,[2] Abderhalden,[3] Mohr,[4] and others have described cases of glycosuria in which as much as 0·4 grm. per litre of that substance has been excreted in the urine. Bergell and Blumenthal[5] also found that tyrosine occurs in the urine of depancreatised dogs. Very little attention appears to have been devoted to other amino-acids, however, or to the total output in various types and grades of glycosuria. This is due, no doubt, largely to the lengthy and laborious processes generally employed for their separation and estimation. During the last few years I have met with several cases of diabetes in which tyrosine crystals appeared in the urine when unfavourable clinical symptoms leading to a fatal issue set in, and it occurred to me that if one could easily obtain even a rough estimation of the amino-acid excretion it would be useful in prognosis and treatment.

The difficulties attending the direct estimation of the acetone bodies in the urine have led to the degree of acidosis being more generally determined indirectly by the amount of ammonia nitrogen passed. For this purpose two methods are commonly employed, Folin's[6] and Malfatti's.[7] In the former the ammonia present in a measured quantity of the urine is aspirated through a known quantity of standard sulphuric acid, and the amount of acid neutralised ascertained by titrating with a standard solution of caustic soda. For this purpose the apparatus shown in the figure is used.

Sketch of apparatus used in the Folin method of estimating ammonia in urine.

A is a wash-bottle containing strong sulphuric acid to remove ammonia from the aspirated air. Into B are placed 25 c.c. of the urine, a few c.c. of paraffin oil (to prevent frothing), and about 1 grm. of anhydrous sodium carbonate. This is at once connected up to C, which contains 25 c.c. of decinormal sulphuric acid, diluted with 25 c.c. of ammonia-free distilled water, and a few drops of a solution of alizarin red. D is loosely packed with wool to prevent any sodium carbonate being carried over, and the other end of the delivery tube is provided with a Folin's absorption apparatus (E) to bring the aspirated air into intimate contact with the acid in C. When the connexions have been made, F is joined up to a filter-pump attached to the water-supply and air drawn through for two hours. At the end of that time the apparatus is disconnected, and E is washed with ammonia-free distilled water into C, the contents of which are then titrated with decinormal sodium hydroxide solution. The figure obtained subtracted from 25, the quantity of decinormal sulphuric acid taken, gives the amount of acid neutralised by the ammonia in the 25 c.c. of urine. To express this as ammonia nitrogen it is multiplied by 0·0014 grm., and from that the percentage and the total ammonia nitrogen in the output of urine for the day can be calculated.

The Malfatti process depends upon the fact that ammonia salts react with formaldehyde in neutral solution to form hexamethylenetetramine, setting free the acids with which the ammonia was combined. These can then be titrated with an alkali. 10 c.c. of the urine are diluted with about 50 c.c. of ammonia-free distilled water and three or four drops of a 1 per cent. alcoholic solution of phenolphthalein added. Decinormal sodium hydroxide solution is run in from a burette and the reading taken when a permanent faint pink colour develops. 3 c.c. of a neutral solution of formaldehyde (prepared by diluting commercial formalin with an equal volume of distilled water, and adding just sufficient decinormal sodium hydroxide to neutralise the mixture, using phenolphthalein as the indicator) are then added, when it will be found that the pink colour disappears. A further addition of decinormal sodium hydroxide is now made until the pink colour is just restored, and the reading is again taken. The difference between the first and second readings is multiplied by 0·0014 grm. and the result by ten to obtain the percentage of "ammonia" nitrogen. From this the content of the 24 hours urine is readily calculated. The addition of neutral potassium oxalate has been shown by Mathison[8] to give a sharper end-point when phenolphthalein is used as the indicator.

Amino-acids react like ammonia to formaldehyde, so that the result obtained by the Malfatti process is the sum of the ammonia and the amino-acids present in the urine, but with Folin's method the ammonia only is estimated. If, therefore, a urine is examined by the two processes the difference between the results will be a measure of the amino-acids present. I have been employing this method of estimating the amino-acid nitrogen for some time and obtained results which have proved of great service in treating diabetes and giving an opinion as to the probable course of my cases.

The amino-acids are comparatively simple chemical bodies of known molecular structure, consisting of an acid, of more or less complex composition, in which an NH_2 group is substituted for one of the hydrogen atoms attached to the carbon atom nearest to the acid radicle. Unlike the proteins, albumoses, and peptones, the amino-acids can be obtained in a pure crystalline form, and constitute the "Bausteine," or building stones, of which the proteins are composed. The varieties and proportions of the amino-acids in different proteins vary considerably, and this, as we shall see later, is a matter of considerable importance in the treatment of diabetes. It has been proved conclusively that the proteins of the food are broken down by the digestive processes into the individual amino-acids of which they are composed, and that it is these, and not, as was at one time supposed, the albumoses and peptones which are absorbed by the walls of the intestine. Their subsequent fate is to a certain extent a matter of speculation, but they undoubtedly constitute the material from which the tissues obtain their supply of nitrogen, and they also contribute to the production of energy. Some observers have maintained that the amino-acids are resynthesised to blood proteins during their passage through the intestinal wall. Others have held that they are partly de-nitrogenised in the course of their absorption, and that the process is carried still further in the liver, the liberated ammonia being converted into urea by the hepatic cells and the non-nitrogenous portion used as a source of energy. A third, and more recent, view is that the amino-acids products of digestion pass into the circulation as such, and are transported to the tissues in the blood-stream; those that are needed for repair of the tissues are then utilised for that purpose, while the unsuitable and unneeded amino-acids are broken down, the nitrogen being converted into urea and the non-nitrogenous portion transformed into dextrose in some instances and in others directly oxidised into carbon dioxide and water like the simple fatty acid constituents of fat, furnishing in either case a source of energy for the organism. Since amino-acids have been most frequently met with in conditions in which there has been serious disease of the liver, such as phosphorus poisoning and

acute yellow atrophy, it has been assumed that the splitting off of nitrogen and formation of urea from the amino-acids not needed for repair purposes by the tissues takes place in the liver, but Folin and his fellow-workers [9] consider that the process is not confined to any particular organ and may be carried out by various tissues, very probably to a preponderating extent by the muscles. In addition to severe hepatic diseases, diabetes, and after extirpation of the pancreas in animals, amino-acids have been met with in the urine in typhoid fever, small-pox, erysipelas, pneumonia, leukæmia, gout, during pregnancy, and in children with gastro-intestinal disorders. In some of these conditions at least the amino-acids found in the urine are not primarily of alimentary origin, but arise from the breaking down of the tissue proteins, and they are excreted in the urine because the quantity formed is too large for the body to deal with in the ordinary way by de-aminisation and oxidation, &c., or the tissues have more or less completely lost their power of splitting some of the amino-acids formed.

The conception of glycosuria as a symptom of a disturbance of metabolism which, although varying in severity, is essentially the same whatever the primary cause may be, is now very generally accepted and has done much to improve our methods of treatment. It is important, however, that we should distinguish two, or possibly three, stages if satisfactory results are to be obtained. In two of the three the defect in metabolism is confined to a more or less complete inability to make use of the sugar derived from carbohydrate foods, but amino-acids are still available as a source of energy, and the body makes use of these, supplemented in the milder forms by a certain amount of sugar derived from starchy foods, and fats for its needs. In the third form, to which the name "diabetes" is confined by some writers, the power to metabolise amino-acids is diminished, with the result that these bodies appear in the urine and gradually increase in amount as the metabolic defect becomes more pronounced. Even in the most serious cases, however, some of the amino-acids are de-aminised and carried as far as dextrose, thus contributing to the sugar excreted in the urine, while the fatty acids of others are imperfectly oxidised and give rise to the acetone bodies (acetone, aceto-acetic acid, and oxybutyric acid) that are passed at the same time. Estimations of the amino-acids, acetone bodies, and sugar give therefore a much more complete picture of the state of the metabolism than any one of these taken alone, and by considering them in conjunction with the effects produced by a diet of which the qualitative and quantitative composition is known we can determine the stage that has been reached and the probable expectation of life.

In this communication I shall confine my remarks to the amino-acids, and only deal with them from the aspect of their determination by the method referred to. The varieties and quantities of the different kinds met with in various types of glycosuria and at successive stages of the condition are matters that are under investigation at the present time. I have found that the urine in simple cases of glycosuria shows no amino-acid nitrogen by the method described, excepting when there is evidence of a gouty condition or serious hepatic derangement; there may then be as much as 0·5 grm. in 24 hours. In such cases the urine may contain traces of acetone, but it is free from aceto-acetic and oxybutyric acids. When secondary disturbances of metabolism occur and the patient has reached the third stage, the amino-acid nitrogen is small in amount at first, 0·05 grm. or less, but as the disease progresses, and especially if it is not controlled by suitable treatment, it generally increases rapidly, often much more rapidly than the acetone bodies, until 2·0 grm. or more are being excreted daily. Finally, the amino acids may be present in such abundance that the relatively insoluble tyrosine crystallises out and can be recognised in the urinary sediment with the microscope. In some cases the excretion of amino-acids and acetone bodies run parallel, but this, as I have just pointed out, is not always the case, and one sometimes meets with a high excretion of acetone bodies and a low amino-acid nitrogen, while other cases show the reverse condition. The former often do surprisingly well, but the latter frequently die suddenly, with symptoms of heart failure, so that as a rule I place more reliance on the amino-acid content of the urine in giving a prognosis, particularly when the output cannot be completely and readily controlled by suitable dieting.

The question of diet is obviously an important one in all cases where amino-acids are found in the urine. It is now generally recognised that many diabetics, and more particularly those of a severe type, do better when the amount of meat taken is strictly limited and intervals of meat-free diet are interposed. This is the basis of the "oatmeal cure," the "potato cure," and similar methods of treatment, and of the vegetable days which are prescribed for most diabetics who are being treated by modern methods. The reason for their use is often not appreciated, however, and they are consequently prescribed in a haphazard manner. Their usefulness really depends upon the different proportions, and to a certain extent the different varieties, of the amino-acids which go to build up proteins of animal and vegetable origin. Animal proteins contain a relative excess of those forms which the defective metabolic powers of the diabetic find it difficult to break down and utilise for purposes of energy production, whereas vegetable proteins are comparatively poor in these constituents as a rule and contain a higher proportion of amino-acids which can be made use of to supply the energy needed by the tissues. Egg protein resembles vegetable protein so far as the diabetic is concerned, so that eggs can be used with safety in many cases where other animal proteins are contra-indicated. The protein of milk comes under the same category as other animal proteins, and one is therefore bound to forbid or strictly limit the use of milk, even when it has been deprived of its sugar, and also the numerous "diabetic" biscuits and bread substitutes which are now largely made of casein in place of the less palatable gluten, by many cases of diabetes.

If we find that the urine of a patient suffering from glycosuria contains amino-acids we must first determine whether these are being derived from the food alone or come from the tissues as well, and if the former, whether he is still able to metabolise vegetable and egg proteins satisfactorily. Should the exclusion of animal proteins of all kinds from the diet result in a disappearance of the amino-acids, as it does in most gouty individuals, the prognosis is hopeful, and it is probable that by carefully regulating the diet, especially with regard to the kind and amount of protein taken, we shall be able gradually to improve the metabolic powers and get rid of the glycosuria, or at least prevents its increase. If, on the other hand, the exclusion of animal protein does not bring about a disappearance of the amino-acids, it may be concluded that the case is one in which there are serious secondary disturbances of metabolism, and that, although the life of the patient may be prolonged for a considerable time if a carefully arranged system of dieting is adopted, the condition is likely to grow worse and ultimately prove fatal. Much may be done even for patients whose condition appears to be almost hopeless if the diet is controlled by thorough and regular analyses of the urine. I have several patients under my care at the present time who have been told by physicians whom they had consulted two, and in one instance three, years ago that they had not many months to live in all probability, but they are still alive and comparatively well. The improvement in their condition has been brought about by a careful adjustment of the diet to their metabolic capacity, and a regulation of the protein and fat intake as well as the amount of carbohydrate consumed. In one of these cases the patient gained 23 pounds in weight in the first five months, and in another 28 pounds in six months, after the diet was rearranged. Others have also put on flesh, but not to such a marked degree. I am strongly of opinion that the common policy of allowing patients with glycosuria an unlimited amount of meat is pernicious in all cases, for even when no amino-acids are being excreted in the urine, and it is evident that they are being utilised by the organism, we should remember the high specific dynamic effect of protein foods, and bear in mind that it has been proved experimentally that a purely protein diet stimulates metabolism 40 per cent. over the fasting standard, as compared with 6 per cent. for carbohydrates and 14 per cent. for fats. A highly protein diet throws work that should be avoided if possible on an already defective organism, and its continuance tends to strain what powers remain to breaking point, with the result that sooner or later amino-acid metabolism fails in most cases, and the third or "true diabetic" stage is reached. The more I see of diabetes the more firmly am I

[9] Journal of Biological Chemistry, 1912, xi., xii.

convinced that the diet of even the mildest cases of glycosuria should be regulated by careful and complete urinary analyses and be so adjusted that no avoidable strain is thrown upon the metabolic powers of the patient in any direction. The appearance of amino-acids in the urine in recognisable amounts is usually a sign that too much protein food is being taken, just as the presence of sugar is an indication that more carbohydrate is being consumed than the patient can deal with efficiently. Their persistent increase, in spite of careful dieting, is of bad prognostic significance, but a steady diminution following a regulation of the protein intake suggests that, with care, the life of the patient may be prolonged for months or even years.

Nottingham-place, W.

THE MORTALITY OF CHILDREN FROM BURNING.

BY WILLIAM A. BREND, M.A. CAMB., M.B., B.SC. LOND.,
LECTURER ON FORENSIC MEDICINE, CHARING CROSS HOSPITAL.

THE deaths here examined are those of infants and children from burning caused by ignition of clothing, lamp accidents, and, in the words of the Registrar-General, "otherwise or not stated how," the great bulk of which may be assumed to have been due to the catching fire of clothing. The following are the actual figures for the years 1906 to 1911:—

Ages.	Boys.	Girls.	Ages.	Boys.	Girls.
0 to 1	214	234	4 to 5	368	775
1 „ 2	443	466	5 „ 10	389	1427
2 „ 3	840	623	10 „ 15	47	369
3 „ 4	580	729	15 „ 20	33	261

In the subjoined chart a small correction has been made for the slightly greater number of boys at the earlier ages than girls. It will be seen that there is a very marked difference between the mortality of boys and girls. In the case of boys the figures increase rapidly up to the age of 3, drop nearly as quickly to the age of 6, and then gradually fall away to almost nothing. The mortality of girls continues to increase up to the age of 5, and then declines, though to not nearly the same extent as among boys. It remains higher through the ages of adolescence, being between the ages of 15 and 20 about eight times as great.

This remarkable difference in the mortality is probably due to the difference in the style of clothing worn by the two sexes. Up to about the age of 3 boys are dressed in the same way as girls. From 3 to 4 they are put into male attire and there is an abrupt and marked fall in the mortality from burning. With girls it is not until the age is reached at which they are better able to take care of themselves that the figures show a decline, though even then, and for later years, they remain much higher than those relating to boys.

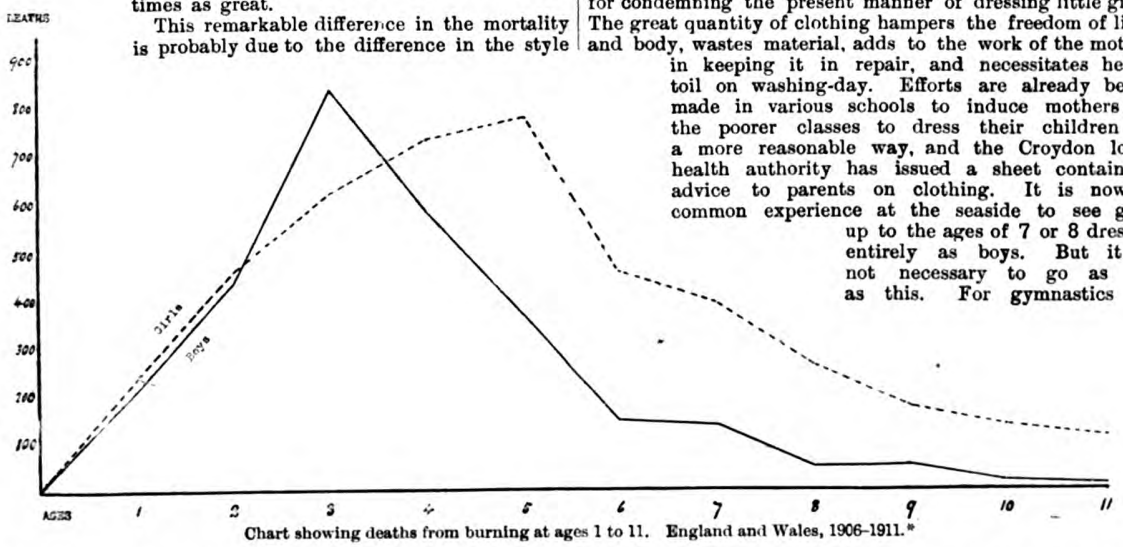

Chart showing deaths from burning at ages 1 to 11. England and Wales, 1906–1911.*

Miss Synge, in her admirable book on children's clothing, has recently drawn attention to the excessive number of garments worn by children of the poorer classes. Speaking of her experience in schools she writes: "The quantity of material used on the children was pitiful. Early Victorian patterns were for the most part used, and underneath the pleats and gathers the children looked swollen and shapeless. ..... The girls are the worst off. First they wear a thick vest and bunchy flannelette chemise. Flannelette drawers over or under some sort of stays—often boned—follow. Then two or three petticoats gathered or pleated into a waistband, or more often attached to a body or two bodies, not infrequently three bodies, of varying sizes. Over this is a bunchy frock, often kilted, and a pinafore. The garments are of varying sizes, some much too tight, some too large, and there is little freedom of limb such as we would see."

Probably no more inflammable arrangement than this, consisting of layers of flimsy material separated by air, could be devised. The corner of a pinafore has only to become ignited and in a moment the little victim is a mass of flames. On the other hand, the inflammability of a boy's costume consisting of cloth knickers and jersey or coat is far less.

Considerable agitation has been directed against the use of flannelette, which is very largely worn, and undoubtedly the cheapest varieties are to be avoided. But this material is inexpensive, and it would probably be difficult to substitute anything for it among the poor. The foregoing figures show that it is not so much the material as the style of clothing which leads to loss of life, and probably any other light material used in the present fashion would be almost as dangerous.

The reason for the higher mortality of boys as compared with girls between 2 and 3 is not quite clear, but it may be due to boys at this age being rather more vigorous and enterprising than girls, and more frequently getting into positions of danger. It might be suggested that the higher mortality among girls at later ages is partly due to their being kept more at home and engaged in culinary work. But against this must be set the greater tendency of boys to play with matches or fire.

In addition to its inflammability there are other reasons for condemning the present manner of dressing little girls. The great quantity of clothing hampers the freedom of limb and body, wastes material, adds to the work of the mother in keeping it in repair, and necessitates heavy toil on washing-day. Efforts are already being made in various schools to induce mothers of the poorer classes to dress their children in a more reasonable way, and the Croydon local health authority has issued a sheet containing advice to parents on clothing. It is now a common experience at the seaside to see girls up to the ages of 7 or 8 dressed entirely as boys. But it is not necessary to go as far as this. For gymnastics or drilling a costume is now worn in many schools consisting of navy serge knickers and a short tunic or jersey and plain serge skirt. This costume is becoming, serviceable, and hygienic, and does not subject the wearers to the risk of injury or death in one of its most terrible forms. These are strong reasons for encouraging its use among the poorer classes in every way possible.

* I am indebted to the Registrar-General for the details of figures for the ages 5 to 11.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PSYCHIATRY.

Pellagra with Insanity.—What is Insanity?

A MEETING of this section was held on Oct. 28th, Sir GEORGE SAVAGE, the President, being in the chair.

Dr. J. W. E. COLE demonstrated a case of Pellagra with Insanity.[1] The patient was a woman who three days after admission to a mental hospital developed an erythema on the bridge of the nose, and this rapidly spread over certain parts of the face. Three weeks later the affected area was covered with a dry, yellowish-brown stain. The scaly surface had a clearly defined red margin, was very symmetrical in distribution, and resembled in every respect a case of severe sunburn. The backs of the hands were deeply pigmented and the epidermis was very rough and coarse. She had a dysenteric form of diarrhœa, but no stomatitis. Her reflexes were definitely exaggerated, but ankle clonus was absent. Her mental condition was difficult to distinguish from dementia præcox. The rash was now disappearing, and with it the mentality was improving. She had been in the asylum, on and off, four years, but the rash had not previously appeared.

Dr. CHARLES A. MERCIER read a paper entitled "What is Insanity?" He said there existed a vague notion of what was meant by insanity, but the fact that this notion had not been satisfactorily reduced to words showed that the concept was unprecise. Insanity and unsoundness of mind were not convertible terms. Each included much which was not in the other; in fact, the two things coincided for only part of the way. Insanity was a disorder not only of mind but of conduct; giddiness, epileptic auræ, claustrophobia, and agoraphobia had nothing to do with insanity. No one dare call a man insane until he had examined his conduct and found it disordered. And in speaking of disorder of conduct he did not mean "disorderly conduct" in the police court sense. But disorder of brain function might be added to the concept, making it a threefold matter; also disorder of metabolism deserved a place, making it fourfold. Each of these concepts was right in its own connexion; confusion ensued from giving all the concepts the same name. If insanity meant disorder of conduct and mind alone, then insanity was a symptom of disorder of brain function. If insanity meant disorder of conduct and mind *plus* disorder of brain function, and if these three were correlated disorders from which the patient suffered, then the three disorders constituted the disease insanity. But if these three were correlated with some wider disorder, such as alcoholic poisoning, myxœdema, gout, specific fever, Graves's disease, this threefold disorder was a sub-disease of the wider disease. When insanity was a symptom only he argued that it was expedient to speak of it as delirium, reserving the name "insanity" for cases in which what was meant by it was a disease.

The paper was discussed by the PRESIDENT, Mr. JAMES STEWART, Dr. PERCY SMITH, Dr. ERNEST JONES, and Dr. E. S. PASMORE, and Dr. MERCIER replied, elaborating his thesis still further.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Chronic Abdominal Pain.

A MEETING of this society was held at the Royal Devon and Exeter Hospital on Oct. 10th, Dr. C. J. VLIELAND, the President, being in the chair. In response to an invitation from the council of the society an address was given by Mr. T. CRISP ENGLISH, who had chosen for his subject "Chronic Abdominal Pain." Mr. Crisp English dealt mainly with the cases in which the cause of the pain was not at first obvious, and in which the question of a laparotomy usually arose. He said that these cases were becoming increasingly common, both in private and in hospital practice. The private patient who had had attacks of pain for some time, in spite of various forms of medical treatment, was sooner or later sent to the surgeon for an opinion; hospital patients were constantly arriving with notes saying that the bearers had had a chronic pain and advising that they should be opened. There was no group of cases in which good sound judgment and common sense were more needed. On the one hand, many patients might be saved years of chronic abdominal pain and ill-health by operation; on the other hand, many patients had been plunged into hopeless invalidism by an ill-considered laparotomy. Speculative operations frequently led to disaster, and were often the forerunner of further operations upon patients who never seemed to get well and who were always ready to have yet another organ explored or excised; but in most cases of chronic abdominal pain there was a definite organic cause for the pain, which could be removed by operation, and if the effects of the pain justified operative measures, then operation should be advised. The most important point was that a thorough physical examination must be made before the best line of treatment was decided upon. Not until evidence of every possible kind had been collected and summarised should diagnosis and treatment be discussed. In this the surgeon must rely upon the coöperation of the medical practitioner and the physician. In hospital practice the diagnostic process was easily arranged, and the following was the usual procedure, say in the case of a patient who had chronic or recurrent abdominal pain, the cause of which was not at first obvious. The history of the case was carefully taken, and the usual physical examination made. The urine was measured for 24 hours and analysed. If there was any doubt about the kidneys or bladder a bacteriological examination was made, for a coli pyelitis was the cause of some cases of obscure pain in the side. Skiagrams were then taken, either of the urinary tract to exclude stone, or of the alimentary tract after the ingestion of a bismuth meal. The patient was referred to the physician in many cases; in doubtful stomach cases a test meal was given and the result analysed. In certain other cases also special investigations were carried out, such as examination with the sigmoidoscope or cystoscope or a blood examination. Further, there might be a difficulty in properly examining the abdomen or pelvis, and an examination must be made under an anæsthetic. There should always be clear definite reason for an examination under an anæsthetic, and it should never be done on the off-chance that something might turn up which could not be discovered without it. The various reports and analyses were brought together after three or four days and these clinical findings were considered as a whole. In this way the diagnosis and treatment could be discussed under the best possible circumstances. Wealthy patients might also have a thorough investigation, but the man of moderate means often could not enjoy the advantages open to the rich and poor, and in his case the question of expense very often meant a limited investigation; this was obviously a matter which urgently needed reform. In taking the history of the illness, the important point was to be quite clear as to the very beginning of the illness: when was the patient last in quite normal health? what was the very first symptom he noticed? The initial symptoms should be gone into carefully and fully, and these would often suggest a clue which could not be picked up in the latter part of the history. The examination of the abdomen should never be hurried. They should look and think before they felt, especially in children. The well-known picture of "The Doctor," by Sir Luke Fildes, expressed perfectly what should be the attitude of the medical man towards the sick child: watching and thinking, and realising that much might be learned whilst the child slept. Skiagrams of the alimentary tract might give very valuable information, but one must confess that in the bulk of cases of chronic abdominal pain they were apt to be disappointing. A great deal had yet to be learned about the meaning of the skiagraphic appearances. Deductions made from skiagrams were often falsified when the abdomen was opened, and skiagrams should only be considered in conjunction with other means of investigation. In reviewing the cases of abdominal pain one noticed at once that there were certain well-marked types and groups. There was the gastric group of cases; there were the men with pain in the right upper abdomen; there were the women with pain in the right side; there were those with suspected appendices; there were the elderly, who might have

[1] THE LANCET, Sept. 6th, 1913, p. 717.

malignant disease; there was that big distressing group of cases whose trouble and often never ended was colitis; and, of course, there were the children in a well-marked group of their own. As regards the gastric group, an important point to remember was that the surgeon should be very wary of exploring the stomach of a patient who did not vomit, however large and splashy the stomach might be, and whatever the skiagrams appeared to show. If, however, there was any suspicion of malignancy, that patient must not be left until the matter was cleared up. Chemical examination of the stomach contents would usually give definite information. Concerning the women with pain in the right side, there were certain points well worth bearing in mind. Gall-stones were unlikely to be present unless there was pain in the back; 20 per cent. of women had some degree of mobility of the right kidney; if a patient was told that she had a movable kidney she would never forget this fact. Trusses and pads applied in the hopes of supporting a mobile kidney often pressed injuriously on the cæcum, damaged the appendix, and so produced a new cause of abdominal pain. One of the greatest harms that could be done to a patient was to tell her that the pain was connected with the ovary; such a statement had often started a condition of chronic introspection, leading to mental and bodily ill-health. In the large group of cases in which the appendix was suspected there were two quite distinct classes. Firstly, these were the cases in which there were mild recurrent attacks of pain and uneasiness, which might be due to slight inflammation of the appendix; and secondly, there were those in which there was chronic inflammation of the appendix producing constant uneasiness in the abdomen and general ill-health. The two conditions might be combined, but the difference between them must be clearly remembered. In the former, if a diagnosis was made of mild attacks of appendicitis, the only wise plan was to have the appendix removed unless there was some good reason to the contrary. He did not suppose that many would dispute this statement nowadays. Under modern conditions the risk of appendicectomy was a long way below a half or even a quarter per cent.; on the other hand, a diseased appendix was a dangerous possession. Definite localised tenderness, especially after the pain had passed off, was usually the sign which clinched the diagnosis, and the man who had pain to-day and tenderness in the right iliac fossa to-morrow had a diseased appendix. Chronic appendicitis was the greatest surgical discovery of recent years, but the disease was surrounded by a host of base imitations, and the surgeon must pick his way carefully when dealing with this subject. No patients were more satisfactory or more grateful than those who had had a chronic diseased appendix removed. The subject of chronic appendicitis had usually been out of health for some time; he was a man who ought to be well and healthy but was not. In a well-marked case the digestion was disordered; pain and distension followed the taking of food; the action of the bowels was erratic, usually constipation with bouts of diarrhœa; tongue furred and breath unpleasant. The abdominal unrest reacted on the general health, which soon suffered. In such a case, if definite evidence of trouble about the appendix was found, a diagnosis might be made of chronic appendicitis, and operation would assuredly restore the patient to good health and enjoyment of life. The full benefit of operation was not always apparent at once and careful after-treatment was essential, but the ultimate results were excellent. The colitis group of cases presented great difficulties. The majority of the patients, unfortunately, could get no help from surgery. For many of them, in fact, the worst thing that could happen was that they should be operated upon. But there was a definite group in which the trouble was associated with an infected appendix. There was no doubt that in certain cases the appendix was the primary focus of infection, and the patient could not be got well by medical means until after the appendix had been removed. The most careful judgment was necessary, for removal of a diseased appendix might be essential to a cure, whilst, if the appendix was normal, the removal of the appendix was likely to do harm. If operation should be decided upon, one point was of great importance: never lead the patient to suppose that removal of the appendix would see the end of all her troubles; operation must be regarded as a preliminary step in a complete scheme of treatment. In children the great majority of cases of abdominal pain were due either to disease of the appendix or to tuberculosis of the lymphatic glands. One of the most striking revelations of abdominal surgery was the frequency of glandular disease in the mesentery. It was a most unfortunate thing for the children of this country that the overcrowded programmes of the Parliamentary sessions prevented the passage of Bills for the control of milk-supply and the inspection of dairies. One of the results was the frequency of abdominal tuberculosis. Chronic appendicitis in children was a very definite disease, and Mr. Crisp English believed was at least as common as acute appendicitis. The text-books contained a scanty reference to this chronic condition, for it was only in the last two or three years that it had emerged from the obscurity of the intestinal disorders of childhood. In the earlier days of appendicitis there was a disinclination to operate upon children in the quiescent stage, unless there had been at least one definite and severe attack. Later clinical observation showed that some of the children with disordered abdomens and unsatisfactory health had, from time to time, attacks of pain and tenderness about the appendix. Removal of the appendix brought about a remarkable improvement in the general health, and so it gradually became clear that these children had been suffering, and suffering very decidedly, from chronic appendicitis. As time had gone by the improvement had been maintained. The children operated upon three or four years ago had never turned back. This was convincing that the appendix was beyond all doubt the cause of ill-health. Once the medical man felt sure about the diagnosis he should advise operation, and this for two reasons. One was that the child would not get well until the appendix was out, and the other was the ever-present risk of an acute attack. Acute appendicitis was one of the worst catastrophes that could befall a child, and once a child's appendix had shown signs of inflammation it should come out. Remove the appendix and the health would at once improve; good spirits and appetite were regained, and the child was once more what Nature meant that child to be.

At the conclusion of his address a hearty vote of thanks was given to Mr. Crisp English on a proposal by Dr. D. W. SAMWAYS, seconded by Mr. RUSSELL COOMBE.

Mr. Crisp English was subsequently the guest of the society at the Exeter and South-Western medical dinner.

LIVERPOOL MEDICAL INSTITUTION.

Aseptic Technique of the Anæsthetist.—Enucleation of the Tonsil.—Suppurative Diseases of the Labyrinth.

A MEETING of this society was held on Oct. 23rd, Mr. ROBERT JONES, the President, being in the chair.

Dr. G. F. R. SMITH read a note on the Aseptic Technique of the Anæsthetist, in which he insisted on the preparation of the patient's mouth, on the use of sterilised apparatus—namely, the mask and its cover, the bottle for the anæsthetic, gag, &c. Also the anæsthetist should wear a sterilised overall, cap, mask, and gauntlets.—Mr. R. C. DUN spoke of the advantages of the method, especially in operations on small children, where the anæsthetist was of necessity close to the field of operation.

Mr. THOMAS GUTHRIE read a note on Enucleation of the Tonsil. Referring to the technique of the operation he preferred the guillotine operation, introduced by Sluder in America and Whillis and Pybus in this country, for the great majority of cases. The method, however, failed in a few cases of very adherent tonsil, and in these he employed blunt dissection and a snare. Discussing the indications for the operation Mr. Guthrie expressed the opinion that in cases of pure hypertrophy of the tonsils in children tonsillotomy was still the operation of choice, provided that not more than the capsule and a thin layer of tonsil tissue were left behind. In such cases a tonsillotomy, properly performed, was almost always sufficient, and was a less severe operation than enucleation. Bleeding after the two operations was as a rule about the same in amount, but there was certainly more risk of troublesome hæmorrhage after enucleation than after tonsillotomy. When repeated inflammatory attacks had occurred and the tonsil was grossly diseased, or was forming the portal of entry for glandular or systemic infection,

enucleation was the only scientific and satisfactory operation. Lantern slides and specimens of tonsils and the instruments used were shown.—Dr. W. SANDERSON, Mr. J. BARK, Mr. C. YORKE, Mr. E. M. STOCKDALE, Mr. A. ADAIR DIGHTON, and Mr. W. THELWALL THOMAS took part in the discussion.

Mr. ADAIR DIGHTON read a paper on Observations on the Diagnosis of the Suppurative Diseases of the Labyrinth. After reminding members of the fact that one of them, Dr. Edgar Stevenson, had introduced labyrinthology into England as far back as 1896, Mr. Adair Dighton demonstrated the tests upon a patient by means of the instruments of Brüning. He then took up in detail the various pathological divisions of labyrinthitis, together with the treatment of them. This completed, he went into the differential diagnosis between labyrinthitis, cerebellar abscess, meningitis and tumour of the auditory nerve. To wind up, he was of opinion that no operation, however small, should be undertaken upon the ear without the preliminary application of the functional tests.—Dr. PANTLAND HICK spoke of a case in which he had been associated with Mr. Adair Dighton where a successful differential diagnosis of cerebellar abscess had been made by the Brüning tests.—Dr. W. B. WARRINGTON said that whilst the nervous mechanism of the vestibular nerve and its relationships to the Deiters group of cells and oculomotor muscles were clearly known, the manner in which different kinds of stimuli excited the several semicircular canals and so caused nystagmus in different directions was difficult to follow, so as to be able to apply readily in practical work. Further simplification of the technique was desirable, especially when it was necessary to examine persons who were ill with intracranial complications. Dr. Warrington alluded to the rarity of cerebellar abscess compared with suppurative disease of the labyrinth, and urged the importance of diagnosis *inter operationem*.—Mr. STOCKDALE said that suppurative middle-ear disease attacked the labyrinth in two positions: (1) the region of the promontory; and (2) the external semicircular canal in the region of the antro-tympanic passage. Total deafness on the affected side would suggest invasion in the cochlear region, and if the auditory apparatus was intact the application of the caloric test would decide whether the semicircular apparatus were active or not. If an erosion of the external canal was found during operation it was usually advisable not to interfere with it. The radical mastoid operation on rare occasions was performed on patients suffering from meningitis. A preliminary lumbar puncture was most helpful in doubtful cases. Deaths from meningitis following a radical mastoid operation and due to lighting up a latent labyrinthitis, although it might occur, was extremely rare.—Dr. EDGAR STEVENSON and Mr. HUGH E. JONES also spoke, and Mr. ADAIR DIGHTON replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The Need for Eugenic Reform.

A JOINT meeting of this society and the Edinburgh Obstetrical Society was held in the hall of the Royal Victoria Dispensary on Oct. 29th to hear an address by Major LEONARD DARWIN, President of the Eugenics Education Society, on "The Need for Eugenic Reform." In introducing the subject Major Darwin said that Linnæus, writing in the middle of the eighteenth century, declared that species were now as numerous as when Providence first created them in the beginning, and that, in accordance with the laws of generation then laid down, the beings originally created produced only forms similar to themselves, with the result that the species now with us were no more numerous than they were at the first. In writing this, this great naturalist was only expressing his belief in the immutability of the different forms of life almost universally held in all civilised countries until the middle of last century. It was true that the suggestion that the world was the outcome of a long series of continuous changes had been made by several philosophers in ancient days; whilst from time to time some more advanced thinker would express the belief that every animal, including man, was the lineal descendant of some more primitive type of living thing. But those who held such views were always so few in number that the general acceptance of their beliefs could only be described as a complete revolution in thought. But must not the adoption of the belief that by evolution alone could we account for the visible facts of life tend to produce material alterations in the way in which we regarded many practical questions? The truth was that it was quite impossible for us to go on acting as if we held precisely the same beliefs as our ancestors, and the aim of the eugenist was both to guide and to hasten the reforms in social customs and in legislation which must in any case result from the acceptance of the doctrine of evolution. Anyone who studied our Poor-law statistics or who looked at our ever-growing lunatic asylums, homes for inbeciles, and hospitals, or who considered our criminal records, or who merely took a single walk in our city slums, must feel profoundly dissatisfied with the existing social conditions of his country. Splendid efforts were no doubt being made on all sides, but when we remembered how long this noble strife had lasted we were absolutely driven to inquire whether some other and hitherto untried methods were not also essential to secure the progress of the nation, or indeed to safeguard it from decadence. If, as Major Darwin held, it would be necessary to continue in the future, as in the past, to try to alleviate or mitigate the sufferings of our fellow creatures by the application of immediate remedies, it would be absolutely incumbent to recognise the necessity of searching for the ultimate sources of all these evils. In the past the efforts of the social reformer had been almost entirely directed to conferring immediate practical benefits on man by altering his mental and physical surroundings. We must, however, also in the future endeavour to ensure that our descendants shall actually enter the world with a better natural equipment than that which we possess. As long as complete ignorance prevailed as to the way in which the generations of man succeeded each other, it was inevitable that all philanthropic efforts to help the human being should have begun at his birth. Now that this ignorance was being dissipated we were bound to see if something could not be accomplished before his birth, and that was the aim of the eugenists. They held that the world was so constituted that all the good qualities of man, as well as all his evil tendencies, had been evolved in accordance with what were called the laws of nature. Their hope and belief was that by studying these laws we should now be able to take steps tending to ensure that the man of the future should be a far nobler being than the man of to-day. Major Darwin said that eugenists were not yet in a position to formulate a policy with great precision. They, however, saw clearly that the selection of the ancestry of the coming generations had been one of nature's main methods of ensuring racial advancement. Nature had always paid the closest attention to heredity, and this study was imperatively imposed on them. It was essential to adopt reforms based on heredity. The breeders of race-horses did not quarrel as to which was the more important for their horses, good training or good pedigree; and the breeders of mankind should not wrangle as to which was the more important, environment or heredity. There was much for eugenists to do, and he rejoiced that a eugenic society was likely to be formed in the capital of Scotland. Galton's definition of the science was that it included "the study of the agencies under social control that may improve or impair the racial qualities of future generations, either physically or mentally." The evil effects of alcohol on the drinker and his family were unquestionable, but how the distant descendants would be affected was unknown. As to the campaign against drink and disease, the eugenist should take part in it. The same was true with regard to environmental reforms, such as better housing and sanitation. But pending further knowledge as to the ultimate effects of all such reforms, if they wanted to ensure the progress of the race they must not confine their efforts to the cure of these evils, but must also consider the factor of heredity, which was the key by means of which the door leading to the future advancement of mankind could be unlocked. Their main object should be to decrease the rate of multiplication in the lower strata of humanity relatively to that in the higher strata. The poorest classes contained many individuals both very virtuous and very capable, whilst amongst the rich many most undesirable specimens were found. A sorting process was always going on, the naturally able amongst the poor often acquiring greater wealth, whilst many of the naturally deficient

amongst the rich slowly sank from their more comfortable estate. The poorest strata did contain an exceptionally large proportion of the biologically unfit, but also had an exceptionally high birth-rate. If this meant that the unfit were multiplying more quickly than the fit, the nation was decadent. Speaking of the remedies for the relatively low rate of multiplication of the more capable classes, he suggested the income-tax being made to vary according to the size of the family, and death duties also. The pay of State employees might be made partly dependent on the number of their children. Such expedients would touch but few, and their main hope must rest on changing the mental attitude of the whole nation with regard to the duties owed to posterity. As to the high fertility of the very unfit, little could be done to check it by moral persuasion. A class did exist, out of which a vast output of undesirable citizens was taking place, which could only be dealt with by sterilisation or segregation. As to the former, he would only say it was a question to be approached with the utmost caution and in a very conservative spirit. They should watch what was taking place in America. As to segregation, this was in the region of practical politics since the passing of the Mental Deficiency Bill, which his society had no hesitation in placing in the forefront of their programme. But besides the feeble-minded other classes of degenerates—e.g., criminals and paupers—ought to have the rate of their multiplication diminished. Habitual criminals and paupers judged to be truly degenerate should be dealt with, not as needing punishment, but as requiring protection against themselves or for safeguarding the public from present injury and future hereditary taint. Their periods of confinement should never be short. Such a system would reduce the output of defectives, and this was all they could hope to do at present. In strengthening the scientific foundations of eugenics much remained to be done. A moral superstructure required to be erected, and here he was convinced their greatest difficulties would arise. Their main object must be to sow broadcast throughout the nation a deep and impelling sense of our obligation towards posterity. Eugenic education societies might be founded in various places, for everyone who enrolled himself was quite unconsciously induced to become an advocate in their favour in general conversation. At Liverpool certain members of the council of the local Eugenic Society had done excellent service in giving elementary lectures in eugenics at various institutions, and, again, help was needed in making the best use of the local press, and lastly, special efforts should be made to interest teachers in schools in their cause. If the eugenic ideal could be properly planted in the minds of all children, not only would the effect be immediately ennobling, but good fruit would in time grow out of this seed by the men and women of the future. In concluding, Major Darwin said that it was not only the help of the scientist and the moralist that they needed, but every class was required to fight against national degeneracy. If it were only more widely known how enormous was the burden thrown on the community by the vast number of degenerates the need for reform would be better understood. Increased taxation, lowered wages, increased prices, diminished aid in time of trouble, and lessened power of competition in time of peace, these were the penalties we were now paying for the carelessness of our ancestors with regard to the purity of our race. Should we pass on this taint with undiminished intensity to posterity? If they could make the facts on which their creed was built more widely known, he was certain they would only have to appeal to their fellow countrymen to attract sufficient recruits to make the success of their cause a certainty.

Sir THOMAS S. CLOUSTON said that Major Darwin's address would give them a stimulus to start a eugenics society in Edinburgh. He was in thorough sympathy with the movement, and said there was no doubt that they had no possible hope of checking the increase in a large number of the mentally defective except through eugenics.

Professor J. COSSAR EWART said those of them who had been interested in questions of heredity were all prepared to help in the formation of such a society as had been suggested. The time must come in the history of all nations when extravagance must come to an end. Hitherto he thought they had been extravagant with their people, and they had not done much to encourage the fit.

Dr. D. BERRY HART said there was a great field for eugenics, and while he agreed in many points with Major Darwin, undoubtedly there were a good many difficulties. For instance, there was a great ignorance as to the laws which determined people to marry. They knew that the marriage of apparently suitable persons did not always turn out very well and that genius was not transmitted. He was exceedingly glad that Major Darwin had given them such a cautious and sane address, but one felt that it was one of the most difficult subjects in the world.

Dr. R. D. CLARKSON (Larbert) also spoke.

Major DARWIN having replied, a provisional committee, with Sir Thomas Clouston as convener, was appointed to take steps with a view to the formation of a eugenics society in Edinburgh.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the session was held on Oct. 24th, Dr. T. Wardrop Griffith, the President, being in the chair.—The President gave an introductory address on the Development of our Knowledge of Diseases of the Heart. He commented on the necessity for those who were working at the newer methods of cardiac investigation to turn at the same time to the work of the older observers, and he passed in review some of the main contributions to our store of knowledge found in the works of Morgagni, Senac, Alan Burns, Corvisart, and Laennec, and among more recent observers John Elliotson, James Hope, Corrigan, and, among the Victorians, Gairdner and Balfour. As a practical result of the employment of the methods of experimental physiology we now had, as aids in our clinical work, the polygraph of James Mackenzie and the electrocardiograph of Einthoven. From former demonstrations the members of the society were more or less familiar with the former of these two instruments; the principles of the latter were explained and reference was made to the valuable work of Dr. Thomas Lewis, who had in this country probably done more than anyone else to advance the utility of the instrument. The address was illustrated by a large number of lantern slides.—The following cases and specimens were shown: Mr. G. Constable Hayes: A case of Syphilitic Disease of the Tonsil, with Glandular Enlargement, Simulating Sarcoma.—Mr. Walter Thompson: A patient with Extensive Rodent Ulcer of the Shoulder.—Dr. W. H. Maxwell Telling and Dr. E. O. Croft: Heart showing large Valvular Clot and Suppurative Pericarditis; Uterus with recent Septic Abortion; (?) relationship between the septic process and the clot; death by pulmonary embolism.—Dr. M. J. Stewart: Section from a case of Myeloid Sarcoma of a Tendon Sheath.—Cases were also shown by Mr. S. W. Daw, Dr. C. W. Vining, Dr. A. L. Whitehead, Mr. J. A. Coupland, and others.

EXETER SANATORIUM FOR TUBERCULOSIS.—This sanatorium in connexion with the Exeter Insurance Committee, was opened last week. The building, which was formerly the Heavitree isolation hospital, will provide accommodation for 12 patients.

NATIONAL HEALTH SOCIETY.—This society is organising a number of courses of instruction which will be given from November until April of next year. At 53, Berners-street, London, W., the offices of the society, there will be courses for women training as sanitary inspectors and health visitors, and also for voluntary health workers among the poor. Private courses in drawing-rooms will be given on first aid, nursing, and personal hygiene, and lectures will be delivered at mothers' meetings, working men's clubs and institutes, and girls' friendly societies on all subjects relating to health, the feeding and general well-being of mothers and infants, boys and girls, and the sanitation of the domestic household. The Lady Priestly Memorial lecture for the year will be given by Professor William Stirling, M.D., on Nov. 27th, at the Royal Society of Medicine, the subject being "Health, Fatigue, and Repose." A course of 12 lectures on Tuberculosis by Dr. J. E. Squire, C.B., was begun on Nov. 3rd at the offices of the society. Applications relating to these lectures should be made to the secretary.

Reviews and Notices of Books.

Die Rassenhygiene in den Vereinigten Staaten von Nordamerika. By GÉZA VON HOFFMANN. Munich: J. F. Lehmann. 1913. Pp. xxi.–237. Price 4 marks.

State Laws Limiting Marriage Selection, Examined in the Light of Eugenics. By CHARLES B. DAVENPORT. Long Island, N.Y.: Eugenics Record Office. Bulletin No. 9. Pp. 66. 1913. Price 40 cents.

AS is well known, America is the country where experiments in legislation for eugenic and other social purposes have been chiefly made, but hitherto there have been no convenient handbooks to which one could refer if in quest of information on the subject. This want has now been supplied by Herr von Hoffmann, who, as the Austrian vice-consul in California, was in a favourable position for collecting the necessary information. But he has not confined himself to a description of the legislative enactments of the Union or of the various States. He has also taken pains to master, as much as possible, what has been said and written for and against them, whether they deal with sterilisation, limitations in marriage, or the selection of immigrants, and with regard to each question involved he has made a clear summary of the *pros* and *cons*. Also to make his book more useful to persons quite unfamiliar with the subject, he begins with a chapter on the principles of race hygiene, but it is questionable whether his treatment of such subjects as the germ-plasm and Mendel's laws is not altogether too brief to be intelligible to a beginner. English readers in any case will have little use for it. More valuable is the next chapter, which describes the agencies concerned in the spread of eugenic ideas in the United States; but perhaps the most useful feature of the whole book is the bibliography which occupies the last 80 pages.

Dr. Davenport's work is of an entirely different nature; its most valuable part is the appendix, which contains a digest of the State laws limiting marriage selection. Their examination in the light of eugenics will hardly serve as a guide for future legislation on the subject, as the method adopted is the simple enumeration of the results of the various kinds of matings which are prohibited in one place or another. For example, with regard to incest between brother and sister, two cases are recorded: 1. "Hannah, about whom nothing is known (except that she has the reputation of not having good sense) had by her brother William, of whom also nothing is known (except that he was a painter) a son ..... of whom someone said he is 'very feeble-minded,' while others have said he is not so bad considering." 2. "The father is feeble-minded—son of an alcoholic criminal. By his sister, who is mentally defective, he had a daughter who is epileptic, alcoholic criminalistic, and without sex control."

What light these two cases throw on the question whether brother and sister marriages are biologically desirable or not, or what use at all it is to discuss the question, it is difficult to see; nor is it easier to follow how by recording the following solitary case any help is given in deciding whether great-uncles and nieces should be allowed to marry. The case is that "Emily R., when 13 years old, was married, for a monetary consideration, to her father's father's brother, who was then 51 years of age. They had three children, of whom the eldest was sexually immoral and died of paresis at 42 years; one boy was 'not bright,' and was drowned at 18 years; the youngest boy died at 2 years."

It must be said in fairness to Dr. Davenport that the treatment of the more urgent question of cousin marriages is far more satisfactory, though the conclusion here arrived at is also based merely on quite a few selected marriages; these are arranged to show that desirable results ensue when the husband and wife sprang from a desirable strain, and that the reverse is the case when the stock is tainted.

Protein and Nutrition: An Investigation. By Dr. M. HINDHEDE. London: Ewart, Seymour, and Co., Limited. Pp. 201. Price 7*s.* 6*d.* net.

THERE is no date on the title-page and the preface is dated 1913, but in that preface it is admitted that the bulk of the present volume was written in Danish in 1905. The author is superintendent of a State laboratory in Copenhagen, where the practical data contained in the book have been worked out, with the coöperation of five assistants. The author admits in his preface that the book is somewhat polemical in character, an admission which will be readily endorsed by every reader.

The volume claims to be an examination of such authorities on dietetics as Voigt, Hirschfeld, Chittenden, and McKay, and the work of each is surveyed in separate chapters. Towards all these investigators, well known to the whole world for their patient efforts in experimental physiology, Dr. Hindhede adopts an attitude of criticism which would carry greater conviction if it were less confused and more controlled. Copious references are given in footnotes, but their value is seriously lessened by the almost complete absence of dates. When we find that some of the literature referred to dates back to 1879, and is alluded to side by side with the results of quite recent work, it is evident that no attempt at sustained analysis is being made. The author singles out Professor McKay for special attack, accusing him of "confusion" of thought, but he has clearly not studied Professor McKay's complete work published in 1912, which embodied the various papers, admittedly tentative, from which the matter is taken for discussion in the volume before us.

The author's own experiments on himself and his laboratory assistants have been on too small a scale to carry much weight, and, like so many of these experiments, they are carried out on selected subjects, losing sight of the possibility that in a population of varying physique, and varying hygienic surroundings, a mixed dietary may be of value.

Physical Diagnosis. By RICHARD C. CABOT, M.D., Assistant Professor of Medicine in Harvard University. Fifth edition, revised and enlarged, with 5 plates and 268 figures in the text. London: Baillière, Tindall, and Cox. 1913. Pp. 519. Price 15*s.* net.

A THOROUGH and practical knowledge of the methods of physical examination and of the significance of the data obtained by them is essential to the practitioner, as affording him some of the most important material on which to base his diagnosis. Instruction in this subject is, therefore, one of the utmost importance for the student. Dr. Cabot's book, which has now reached its fifth edition, has achieved a recognised position as a standard manual upon the subject. In our reviews of some of the former editions we have referred to the practical and eclectic character of the information given, and these features are maintained in the present one. Dr. Cabot does not describe any method of examination with which he has not had practical experience. He devotes himself to physical examination proper, and deprecates any distinction between clinical diagnosis and laboratory diagnosis. He prefers to consider all the methods together, and advises that the student should be accustomed to think of them and practise them in close relationship to one another. For this reason he includes descriptions of the analysis of the gastric contents, of the blood, and of the urine.

The arrangement of the subject matter is convenient and simply worked out. Data relating to the body as a whole, such as alterations in weight and variations in temperature, are first considered, and then the various regions, systems,

or organs of the body are separately discussed. The information obtainable by percussion and auscultation is very thoroughly described in connexion with the examination of the heart and lungs. Dr. Cabot often gives some valuable statistics in support of the statements he makes. We know of no book in which these methods are more clearly described or in which the significance of the signs obtained by them is more critically discussed.

Among the additions to the present edition we may mention the sections upon arteriograms, phlebograms, and electrocardiograms. Dr. Cabot here only gives a brief *résumé* of the results so far obtained from them, and does not furnish any information as to the methods of obtaining them. He also gives more details in regard to the arrhythmias in the light of recent work upon their nature. In connexion with the examination of the pulse he devotes special attention to the subject of blood pressure and to the instruments for measuring it. The examination of the stomach by means of the X rays after the administration of a bismuth meal is adequately dealt with, and some reproductions of radiograms illustrating the results obtained are given. The subject of interlobar empyema is well described and is illustrated by a very good reproduction of a radiogram of a case observed by Dr. Englebach and Dr. Carman.

The book is well produced and clearly printed. The number of the illustrations has been increased, and their quality has been greatly improved. They now form a valuable addition to the usefulness of the book. We can commend it to students and practitioners as a reliable and interesting work upon an important subject.

Massage, its Principles and Technic. By MAX BÖHM, M.D. Berlin. Edited with an introduction by CHAS. F. PAINTER, M.D., Professor of Orthopædic Surgery at Tufts College Medical School, Boston. Illustrated. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 91. Price 7*s.* 6*d.* net.

IN his introduction the editor states that "physical therapeutics in all its forms is employed far more widely in Germany than in America." It is probably employed far more widely in America than in England. The profession at large are not securing for their patients the benefits that they might, because they do not know enough of the advantages to be gained from massage and exercise to think of making use of such measures, nor are the principles which underly the use of exercises in surgery at all widely appreciated. We are glad, therefore, to see the present large output of books upon this subject. They differ little from each other in their contents, but they all tend to make more widely known the good effects that can be obtained from the skilful application of massage in numerous affections.

We are in entire agreement with Dr. Böhm when he says that in a great many cases, in order to avoid harm, massage should be carried out by the surgeon himself or under his eye; such cases are especially those of inflammatory conditions of muscles, tendons, joints, and nerves, massage of internal organs, the eye, the larynx, &c. But there is unquestionably a large field open to the masseur with no special medical knowledge, as, for instance, when massage is administered to practically sound parts to strengthen them or improve their nutrition. The skilled masseur equipped with a small knowledge of anatomy is fully equal to this task. The book under consideration deals only with the latter class of case. It is intended for the student who desires to assist the surgeon in an intelligent manner in massage and gymnastics. The technique described is essentially that prescribed in Professor Hoffa's clinic. After a description of the preparation of the patient and the fundamental manipulations of massage a few general contra-indications are given, and then follow a systematic description of massage as applied to each of the joints, to the groups of muscles in the trunk and limbs, a chapter on the massage of the nerves and skin, and finally on body massage. Coming from the clinic of Professor Hoffa it is unnecessary to state that the methods described are of the most approved and scientific. The arrangement of the subject is the best that we have seen, in that the contra-indications as applied to each joint are clearly stated at the beginning of each section; then follows an equally clear statement of the indications and the most suitable technique for the joint in question. The illustrations, upon which the book so largely depends for its value to practitioners and those unfamiliar with massage, are clear, simple, and well reproduced.

We can recommend this book, which from its moderate cost and wide usefulness deserves to find a large public in this country.

The Surgery of the Eye. By ERVIN TÖRÖK, M.D., Surgeon to the New York Ophthalmic and Aural Institute, &c.; and GERALD H. GROUT, M.D., Assistant Surgeon to the New York Ophthalmic and Aural Institute, &c. With 509 original illustrations, 101 in colours and two coloured plates. London: Baillière, Tindall, and Cox. 1913. Pp. 507. Price 18*s.* net.

THIS is in appearance a sumptuous work, with all the superficial attractions of good print and profuse illustrations. Closer acquaintance with the contents, however, proves disappointing. We find that the inflated number of illustrations is largely due to repetition of the same blocks. It is true that these are good—as good as any photographs of operations from nature that we remember to have seen; but photographs from nature are on too small a scale to be satisfactory guides to students, and it is impossible by these means to obtain that sharpness and accuracy of detail which are all-essential in operations upon the eye. The authors appear to have realised this point, for they have added many good diagrams.

With the letterpress we are disappointed. Not that there are many actual errors—we have come across only one bad recommendation, viz., paracentesis of the cornea for acute inflammatory glaucoma (p. 175). The great fault is that the operations are not described in sufficient detail. The book is intended as a treatise on ophthalmic surgery for students and practitioners, and as such it ought to emphasise those minutiæ of technique which are more important in this than in any other branch of surgery. This lack of attention to the small details of every step is the besetting sin of the now numerous text-books on ophthalmic surgery. The great book on this subject yet remains to be written. The authors have used the designations "European" and "American" to distinguish the methods of operating from before and from behind the patient respectively. They are apparently unaware that nearly all English surgeons adopt the so-called "American" method, and that the so-called "European" method is by no means universal on the Continent. Most of the ordinary operations are described and instruments are illustrated.

Statistical Ready Reckoner. By GERARD C. TAYLOR, M.A., M.D. Cantab., D.P.H., Medical Officer of Health of Berkshire. Reading: Bradley and Sons. 1913. Pp. 409. Price 12*s.* 6*d.*

PRESUMABLY this book is intended for the use of junior members of the Public Health Service, or of others whose leisure is so limited as to render such a *vade mecum* serviceable. The value of the set of tables that form the bulk of this volume has been proved by the author, who has used them in calculating the statistical rates required in his own work as county medical officer of health of Berkshire; and

he publishes them with a view of facilitating the arithmetical labour of others similarly circumstanced.

The tables are prefaced by a set of examples showing how the former may be used most expeditiously. These examples appear to be correctly worked out, and the ready reckoner may be serviceable to those who are not familiar with the use of the ordinary logarithmic tables. We have not examined the 400 pages of tables that form the bulk of this volume, but the author affirms that great care has been taken, both in their preparation and in the correction of the proof-sheets, and trusts that no serious errors have been overlooked. The following suggestions are offered to those using the ready reckoner for the first time. In the first column of each page the population numbers in the tables are arranged consecutively, the figures in heavy type printed at the head of the other columns indicating the number of events (births, deaths, &c.) corresponding to the rates per 1000 of the population. In order to keep the volume within convenient limits the populations above 10,000 have not been included; but inasmuch as the rates for any larger populations may be calculated from the tables by merely adjusting the decimal point nothing is sacrificed by this omission.

Abwehrfermente des thierischen Organismus gegen körper-, blutplasma- und zellfremde Stoffe, ihr Nachweis und ihr diagnostiche Bedeutung zur Prüfung der Funktion der einzelnen Organe. Von EMIL ABDERHALDEN, Direktor des Physiologischen Institutes der Universität zu Halle a.S. Mit 11 Text-figuren, 1 Tafel. 2. Vermehrte Auflage. Berlin: Julius Springer. 1913. Pp. 199. Price, paper, 5.60 marks; bound, 6.40 marks.

WRITING on June 15th, 1913, the author hopes that the second edition of his work will have as friendly a reception as the first edition. The original title of the work, which was very fully reviewed in THE LANCET of Jan. 4th, 1913, has been changed. The term "Schutzfermente" has been replaced by the title "Abwehrfermente." The illustrations have been increased from 8 to 11, a plate is added to show the arrangement adopted for cooling the polarisation tubes, while the text has been increased from 110 to 199 pages. The literature also has been added to. The text has been thoroughly revised and many additions have been made, but we still could have wished to see the text so set out that the reader could find his way more readily, especially as there is no index. New chapters have been added on the stages in the katabolism of the "Bausteine" of the organism, hermaphroditismus verus, the protective regulations of the animal organism against substances foreign to the blood plasma, preliminary studies on the ferments of normal blood, the formation and sources of protective ferments, anaphylaxy, sero-diagnosis of the functions of organs, the correlation of certain organs. The unity of so-called proteolytic ferments is doubtful. Very full technical descriptions are given of the methods of dialysis adopted and also of the optical methods used by the author. We wish the second edition as rapid a success as its predecessor.

Diseases of the Eye: a Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. DE SCHWEINITZ, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, &c. With 360 illustrations and 7 chromo-lithographic plates. Seventh edition, thoroughly revised. London and Philadelphia: W. B. Saunders Company. Pp. 979. 1913.

THERE is no need for us to reiterate the eulogies with which we have greeted previous editions of this work. It is one of the great standard text-books of the English-speaking medical world, and the new edition serves but to re-establish it more firmly. We think the time has come to alter its *format:* it would be much handier if the pages were rather larger. Its outstanding merit is the abundant reference to all the most valuable contributions to the literature of the subject in recent years, and Dr. de Schweinitz succeeds in incorporating these details without marring the general perspective—no easy task. The new matter comprises paragraphs on Schiötz's tonometer, ophthalmodiaphanoscopy, sporotrichosis, Widmark's conjunctivitis, rosacea keratitis, epithelial dystrophy of the cornea, blue sclerotics, progressive atrophy of the iris layers, exudative retinitis, angiomatosis retinæ, cysts of the retina, blindness from arylarsenates, Siegrist's local anæsthesia, trephining of the sclerotic, Reese's muscle resection operation, and Toti's operation (dacryocystorhinostomia). Vaccine therapy and the indications for the administration of salvarsan receive ample consideration, and special attention has been paid to diseases of septic origin, particularly the more obscure forms of iritis and uveitis. The author's apologies for the shortcomings of his work are sufficiently discounted by the list of editions and reprints which have been found necessary. We can cordially recommend the book as belonging to the small group of the very best text-books on ophthalmology.

LIBRARY TABLE.

Die Fermente und Ihre Wirkungen. Von Professor CARL OPPENHEIMER, Dr. Phil. et Med., Berlin-Grunewald. Band I., vierte völlig umgearbeitete Auflage; und Band II., vierte völlig neubearbeitete Auflage. Nebst einem Sonderkapitel: *Physikalische Chemie der Fermente und Fermentwirkungen.* Von Professor R. O. HERZOG, in Prag. Leipzig: F. C. W. Vogel. 1913. Band I., pp. 485, price, paper 20 marks; bound 21.50 marks. Band II., pp. 1150, price, paper 36 marks, bound 37.50 marks.—The importance of ferments in the great vital processes of the body is now established. They may form, for example, a defence against bacterial invasion and they are concerned in controlling the physiological activities connected with metabolism. The study of ferments is developing very rapidly, and knowledge in regard to these wonderful bodies of the most interesting kind is being accumulated day by day. Biochemistry, indeed, has for its foundations the study of the enzymes and their functions. The ground is well covered in this extensive work upon the subject, the two volumes presenting an exhaustive reference to modern researches. The work is divided into three parts, the first being devoted to the general chemistry and biology of the ferments, the second to the individual ferments, and the third to the chemico-physics of the ferments and the nature of their reaction. This last interesting part is written by Professor R. O. Herzog. The subdivision of these parts into chapters and subsections resolves the enzymes into an excellent system of classification. The references to modern contributions on the subject are very copious, and disclose the fact that no small share of the pioneer work may be allotted to English workers. Prominent among these stand the names of Bayliss and Starling, Vernon, Green, Brown, Morris and Heron, White, Pavy, Plimmer, and O'Sullivan. The real founder of biochemistry, however, was, of course, Pasteur, and a rapid development of his work appeared in the researches of Fischer, Buchner, Kühne, and Chittenden. The history of the enzymes is a most interesting one, and all those who would be conversant with this history, as well as with the medical, chemical, and physical significances of the enzyme in the light of modern research, will consult this work with an obvious gain to their knowledge.

The Further Evolution of Man. By W. HALL CALVERT, M.D. Edin. London: A. C. Fifield. 1913. Pp. 324. Price 5*s.* net.—The first few chapters of this book are devoted to an attack upon the Darwinian hypothesis, in so far as that purports to find in natural selection and the struggle for existence a quasi-mechanical basis for the teleological aspect of evolution. In regard to this part of the book Dr. Calvert frankly admits that it is very largely based upon Paulin's work,[1] particularly Chapters III. and V., which deal with the Cannibal Habit in the Male and Malthusianism and the Law of Population. Darwin, with his usual frankness, admitted that he had been unable to ascertain the precise influences by which the assumed tendency of species to increase beyond the means of subsistence is checked, but in default of evidence concluded that the numbers are kept down mainly by starvation and disease. As against this conclusion, which may be called the bedrock tenet of Darwinism, Paulin claimed to have proved the practical universality among all prolific animals of an instinct prompting the male to devour its mate's offspring if it can obtain access to them within a certain number of days after birth. To Dr. Calvert's exposition of Paulin's theory of male cannibalism as a check to undue increase we have referred in a previous issue,[2] in connexion with Mr. Rodier's suggestion for the utilisation of this instinct as a means of exterminating rats. There can be no doubt of the interest and importance of this theory, as the influence of natural selection in the moulding of species by survival value would be reduced almost to vanishing point, once it were proved that the elimination of the "unfit" by starvation or disease is the exception and not the rule in nature. Darwin's views were admittedly suggested by the work of Malthus, whose alleged "law of population" was destructively criticised by Paulin. Dr. Calvert, in a chapter which reproduces the main facts upon which this criticism is based, asserts that Paulin "has proved that population never tends to outrun the means of subsistence; that population recedes when industry and commerce do, and rises again with a period of commercial prosperity. He has shown that war, pestilence, and famine do not limit population; that, in fact, they act at once automatically as an incentive to an increased birth-rate." These points disposed of, Dr. Calvert passes on to the main object of his book—"to ascertain from observed phenomena what is the path which man must follow, and to forecast as nearly as possible his final goal." It is an ambitious programme, and we are bound to say that we are by no means satisfied that it has been adequately carried out. The view taken is that, through the growth of "altruism," due to the permeation of society by the Christian ideal, there has been initiated a progressive amelioration of the general conditions of life, destined to culminate in a universal *régime* of harmony and happiness. It is a very dubious psychology which draws a hard-and-fast line between "egoism" and "altruism," as if they never coincided or had nothing in common. And, in any case, it is at least as tenable that the economic changes applauded by the author are due to the increased egoism of the many who profit by them, as to the growth of altruism among the few who, in a material sense at least, stand to lose thereby.

The Proceedings of the Optical Convention, 1912. Held at South Kensington, June 19th to 26th, 1912. Vol. II. 1912. London: University of London Press. Price 10*s.* net.—For reasons which need not be entered into now ophthalmologists in general hold aloof from the Optical Convention. Without prejudice to the validity of their position, we cannot but regret the detriment which it entails. It cuts them off in large measure from practical acquaintance with the work of such distinguished physicists as Professor R. T. Glazebrook, Professor Silvanus Thompson, Professor Callandar, Professor Poynting, Professor Schuster, and others too numerous to mention. It is the more necessary, therefore, that ophthalmologists should peruse the published accounts of the proceedings of those especially working at the problems of pure optics. There are many in this volume which will well repay their trouble. They will find Professor Silvanus Thompson's presidential address replete with interesting matter. It is an excellent *résumé* of the history of optics to the present day. We would further especially invite their attention to Messrs. C. C. Paterson and B. P. Dudding's contribution on the Visibility of Point Sources of Light, to Messrs. J. S. Dow and V. H. Mackinney's paper on the Measurement of Light and Illumination, to Dr. F. W. Edridge-Green's new Spectral Colour-mixing Apparatus, Mr. Tomlinson's Scotomagraph, Dr. von Rohr's paper on Aspherical Surfaces for Spectacle Lenses (Gullstrand's cataract lenses), and Messrs. A. C. Jolly and A. J. Bull's communication on the Measurement of Colour. These will suffice to show that the work of the physicist should not be neglected, and they will further afford evidence, if such be needed, that the physicist's *ex cathedrâ* statements require the physiologist's criticism.

Die Halluzination: Ihre Entstehung, ihre Ursachen, und ihre Realität. Von Privatdozent Dr. KURT GOLDSTEIN, in Königsberg. Wiesbaden: J. F. Bergmann. 1913. Pp. 72. Price 2*s.* 3*d.*—Dr. Goldstein has written a useful brochure on the subject of hallucinations. He explains them as due to the abnormal excitability of the particular sense within whose field they occur. Illustrations are given of the various types of hallucination. In this connexion we should have liked to see more investigation of the hallucinations of the muscular sense. The factors concerned in the production of hallucinations are fully dealt with, and there are interesting references to the hallucinations of various figures prominent in the world's history. The paragraphs on the hallucinations of individuals who are mentally normal will repay perusal—a subject on which the Society for Psychical Research made a series of investigations some years ago.

Medical Electricity and Light. By ETTIE SAYER, M.B., B.S. Lond. London: The Scientific Press, Limited. 1913. Pp. 124. Price 3*s.* 6*d.* net.—This is an elementary text-book for nurses, and naturally treats the rather extensive subjects comprised in the title in the shortest and simplest manner. Its main object is to form a guide to nurses so that they may the more intelligently assist the practitioner or specialist for whom they are working. Most forms of treatment and apparatus are described, and the book is fully illustrated, even to the extent of redundancy. It will no doubt be found of real use to those for whom it is intended, but for the professional man it cannot be said to have any value.

Laws (Abstract) and Board Rulings Regulating the Practice of Medicine in the United States and Elsewhere. Twenty-first edition. Chicago: American Medical Association. 1913. Pp. 196. Price 30 cents.—The scope of this extremely useful pamphlet has been increased, so that in addition to Canada and the United States it now contains an abstract of the licensing laws relating to the practice of medicine in all the principal countries in the world. There is also a list of the medical colleges of all countries. It is, of course, most detailed in regard to the conditions for practice in the various States of the United States (each of which has its own regulations, so that a separate licence to practise is necessary for each State). Here it gives under the several States the licensing authority and its *personnel*, the

[1] No Struggle for Existence; No Natural Selection. By George Paulin. Edinburgh: T. T. Clark. 1908.
[2] THE LANCET, Sept. 6th, 1913, p. 779, "Rat Destruction."

dates when examinations are held, the requirements to accompany an application for licence, the standard required of colleges by the State, exemptions, reciprocity of licence with other States, and the definition of the Act as to what constitutes the practice of medicine. The book will prove invaluable to any medical man contemplating practice in the United States, and is serviceable generally as a book of reference to conditions of medical practice throughout the world. Every care has been taken by the Council of Medical Education of the Association to secure the utmost possible accuracy.

MISCELLANEOUS VOLUMES.

PROMPTITUDE in publishing its Transactions is a great virtue in any conference, and we are glad to welcome the *Transactions of the Fifth Annual Conference* (London: Adlard and Son. 1913. Pp. 222. Price 4*s*. 6*d*., post free 5*s*.) of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis, which was held on August 4th and 5th. Owing to its coincidence with the International Medical Congress, which followed immediately after the British Medical Association, we were unable to devote space to a report of the conference, but undoubtedly the chief interest centred in the discussion on tuberculin treatment, and this discussion was fully reviewed in a leading article in our issue of August 23rd, in which Dr. Hector Mackenzie's general survey of the subject also was published, several other papers having been published in previous issues of THE LANCET. The other papers contained in the Transactions discussed various aspects of coördination of antituberculous measures by Sir Robert Philip, Councillor A. Neal, Dr. A. Ransome, Dr. Hermann Biggs, Dr. W. C. White, Dr. E. Rist, Sir Clifford Allbutt, Professor C. Saugman, Sir William J. Thompson, Dr. E. Coey Bigger, Professor W. H. Thompson, and Lewis Courtauld.—The fact that a little pamphlet, entitled *Preventive Hygiene, an Account of the Brussels International Conferences, 1899 and 1902*, by an ENGLISH MEMBER (London: John Bale, Sons, and Danielsson. 1912. Pp. 36. Price 3*d*.), has reached a fourth edition, shows clearly that many have been anxious to learn the results of these two conferences on the prevention of venereal disease, and as the matter is exciting special attention at the present time we may state that this book presents very clearly one aspect of this important subject. It is not bigoted, and it recognises that the question has many sides, so that it should prove of help to those who wish to know the truth about the methods of the prevention of venereal disease and their results.

A number of reference books claim attention. University calendars contain much information of general interest, more especially at the present moment, when reform is in the air and thought is being devoted to educational matters generally, and the purpose and place of examinations in particular.—We have received the *University of London Calendar, 1913–14* (London: Hodder and Stoughton. Price 6*s*. net), which, in addition to the usual information contained in this class of books with regard to curricula, names of members of the various faculties, and so forth, is prefaced by a short history of the University, and includes a coloured map of London showing the constituent colleges and the institutions having teachers recognised by the University.—The *Regulations for External Students* and the *Regulations for Internal Students* (same publishers) are useful and necessary supplements to the University calendar.—*London Matriculation Directory* (London: University Tutorial Press, Limited, price 1*s*. net) gives the questions set at the September examinations, with answers.—*London University Guide* (London: University Correspondence College, published gratis) contains notes on the subjects of the different examinations, with notes on the special subjects, for 1914–15.—*University College (London) Calendar* (London: Taylor and Francis) contains, in addition to the usual information, the examination papers for the session 1912–13.—Other calendars for the new academic year are those of the *University of Durham College of Medicine* (Newcastle-on-Tyne: Andrew Reid and Co., Limited), the *Calendar of the University of Bristol* (to be obtained from the Registrar of the University), and the *Calendar of the National University of Ireland* (also to be obtained from the Registrar). In the last named several changes are announced in the courses and regulations for 1914.—*The Calendar of the Royal College of Surgeons of England* (London: Taylor and Francis, price 1*s*.) has also just been issued. Alterations in the regulations will be found in the annual report of the Council of the College published in THE LANCET of Oct. 18th, p. 1144.

The increasing vigilance of the income-tax authorities is no doubt responsible for the issue of new editions of *Income-Tax Simplified*, by ARTHUR FIELDHOUSE and E. EWART FIELDHOUSE (London: Simpkin, Marshall, and Co., price 1*s*.), and *Guide to the Income-tax*, by F. B. LEEMING (London: Effingham Wilson, price 2*s*. 6*d*.). Both works serve a useful purpose; but we still look for the book—a small one would suffice—specially written to cover the requirements of the average general practitioner.

JOURNALS AND MAGAZINES.

Parasitology. Edited by GEORGE H. F. NUTTALL, F.R.S., and ARTHUR E. SHIPLEY, F.R.S., assisted by EDWARD HINDLE, Ph.D. Vol. VI., No. 3. October, 1913. London: C. F. Clay, Cambridge University Press. Price 10*s*. net; yearly subscription £1 10*s*.—The opening article on the Anatomy of Argas Persicus (Oken, 1818), by L. E. Robinson and J. Davidson, consists of the second part of these authors' exhaustive monograph on the fowl tick. The present part is devoted to an account of the integument, alimentary canal, and the blood vascular, respiratory, and excretory systems, and is profusely illustrated both with diagrams and coloured plates.—The Nuclear Structure and the Sporulation of Agrippina Bona Strickland, by Kenneth R. Lewin, contains an account of the nuclear changes of a gregarine, parasitic in the larva of the rat-flea, Ceratophyllus fasciatus. The various stages in the formation of gametes and the subsequent sporulation are described in detail, and from his account it appears that Agrippina bona does not differ materially from other gregarines in the manner in which the spores are formed.—In an article on Some Peculiar and Probably Specific Bodies in the Erythrocytes in Rinderpest and another Allied Disease, by W. Leonard Braddon, the author describes certain peculiar appearances observed in the blood of animals infected with rinderpest. In order to produce these appearances the blood is mixed with a solution of 1 per cent. potassium citrate and 0·5 per cent. medicinal methylene blue, and of the resulting mixture some specimens are put up under cover-glasses, whilst others are put in watch-glasses exposed to the air but not to light, and arranged as moist chambers. Under these conditions, after periods varying from 6 to 48 hours, peculiar bodies, ranging in shape from dots up to irregular elongate rods projecting from each side of a corpuscle, make their appearance in the red cells of animals infected with rinderpest. These bodies have so far been detected only in the blood of animals suffering from rinderpest or but recently recovered from it; on the other hand, they have never been observed in the blood of normal animals, so that it seems reasonable to assume that they are specifically related to rinderpest,

At the end of the paper Sir William Leishman and Professor Minchin add notes, in which they testify to the accuracy of Dr. Braddon's description of the appearances presented in stained preparations of infected blood, but remark that these bodies do not resemble any bacterial or protozoal parasite hitherto known.—Observations on Mammalian Erythrocytes, by J. Charles Johnson, contains the results of a series of examinations of blood-films of both normal and diseased mammals, undertaken in order to determine whether the appearances described by Braddon could be seen in other animals. The blood corpuscles from various sources never presented anything like his description of the alleged parasite of rinderpest, which tends to support Braddon's view that what he describes is specific to that disease.—Tri-radiate Tænia Crassicollis Rud, by S. O. Yoshida, consists of a short note on the prismatic malformation of this species of tape-worm, occurring in Japan.—Seymour Hadwen contributes a most interesting article on Tick Paralysis in Sheep and Man Following Bites of Dermacentor Venustus, accompanied with notes on the biology of the tick. For some time past complaints had been received from a sheep farmer in British Columbia about a form of paralysis affecting his sheep and occurring annually from late February to early April. Dr. Hadwen has investigated this disease experimentally, and finds that it is a form of paralysis occurring in sheep, man, and probably other animals, and is caused by the bites of Dermacentor venustus, one of the common ticks of Western America. The author was able to reproduce the disease by the bites of adult ticks. The resulting paralysis in lambs was found to develop from six to seven days after the ticks had been placed on the aninmal. "Tick paralysis" is usually of short duration and is benign in character, but occasionally it may persist for long periods and may terminate fatally. The causative agent has not been discovered, and the disease has not been reproduced by inoculation. The most likely hypothesis seems to be that the tick injects a toxin which gives rise to the symptoms, and in this respect it is interesting to note that the ticks usually attach themselves along the backbone of animals. Finally, six cases are mentioned of tick-bites in children being followed by paralysis, in one of which the child died suddenly with symptoms of acute ascending paralysis. After death a large tick was found at the nape of the neck. Photographs are given showing the marked paralysis produced in lambs by the bites of ticks.—Experimental "Tick Paralysis" in the Dog, by Seymour Hadwen and G. H. F. Nuttall, is supplementary to the foregoing paper, and records a positive experiment carried out at the Quick Laboratory, Cambridge, upon a dog experimentally infested with Dermacentor venustus obtained from Canada. A single female tick was placed on this dog and after eight days the animal became paralysed; the symptoms persisted for about five days, after which they subsided and the dog recovered. In addition, guinea-pigs that had been bitten by nymphs and larvæ of Dermacentor venustus were found to die five to seven days later. As the disease is never accompanied by fever and, moreover, cannot be reproduced by inoculations, it seems probable that it is not infective.—The Herter Lecture, III., Piroplasmosis, by George H. F. Nuttall, consists of a useful summary of our knowledge of this important group of diseases, with descriptions of the various parasites and their life-histories, and also methods of treatment and prevention.—Conditions Influencing the Transmission of East Coast Fever, by George H. F. Nuttall and Edward Hindle, comprises a brief account of the effect of certain conditions on the infectivity of ticks infected with Theileria parva. The authors find that infected ticks when feeding on cattle do not produce infection during the first two days, and are still infective after feeding on a rabbit for three days. The partial feeding for two days followed by starvation for 17 days renders them non-infective. Infective ticks were rendered non-infective by exposure to 10° C. for three weeks, but their infectivity was restored by subsequently warming them. The authors suggest that the final development of Theileria parva in the tick, resulting in the latter becoming infective, commences only after the tick has begun to ingest blood.

The Journal of Laryngology, Rhinology, and Otology.—The October issue contains a paper read by Professor E. J. Moure, of Bordeaux, in the Laryngological Section of the recent International Congress of Medicine, on What becomes of Sinuses that have been Operated on? The sinuses referred to are, of course, the accessory sinuses of the nose. Many consider that in order to clear out and eradicate suppuration satisfactorily from a frontal sinus full exposure by destruction of its entire anterior wall, commonly known as Kuhnt's procedure, is indispensable, with the object of bringing the skin into contact with the internal wall of the sinus in such a way as to lead to the complete occlusion of its cavity, whilst Killian has devised an operation going a step further to obtain this apparently indispensable fusion. Professor Moure has long been quite convinced that these different ideas are more theoretical than practical, for he has observed that antra which had been very roomy when first operated upon no longer existed, so to speak, when he had to operate for the second time. The cavities had become filled up with fibrous tissue; even the bony walls had come nearer to one another, so that the sinus, in a measure, had disappeared. This fact—the cicatricial obliteration of the sinuses—at once suggested the question, If sinuses after operation close and fill up, then why perform operations so extensive and disfiguring as those of Kuhnt and Killian? For this reason Professor Moure believes that the Caldwell-Luc operation in the case of the maxillary antrum, and the Ogston-Luc in the case of the frontal sinus, will always be the ideal operations when these suppurating cavities must be dealt with by the external route. This is a matter of capital importance, since it means the reduction to a minimum of deforming and mutilating operations, and lessens the gravity of operative acts which many practitioners hesitate to perform by reason of the unfortunate consequences which they have had at times to deplore.

The British Journal of Inebriety.—The October number publishes in full the excellently practical and thoughtful address on Alcohol and the Child-Bearing Woman, delivered by Mrs. Mary Scharlieb, M.D., at the breakfast of the National Temperance League in connexion with the Brighton meeting of the British Medical Association, of which an abstract was given in THE LANCET of August 2nd, p. 293. In an article on Parental Example and Intemperance, the Rev. Professor W. F. Lofthouse summarises the results of an inquiry which he has carried out on this subject by the method of the questionnaire. The replies received appear to have been somewhat indefinite and on some points contradictory, but they showed at all events that the influence of parental example may possibly cause reaction instead of imitation, so that drunkenness in the parents may lead to fanatical teetotalism in the children. An inquiry of this sort if carried out on a wider scale and with more precaution against subjective influences might be of value. In the course of some brief remarks on the Psychological Aspects of the Alcohol Problem, Dr. G. E. Partridge pleads for the abandonment of the naïve ethical judgments which have played so large a part in the discussion of the liquor problem, and outlines a scheme of psychological inquiry into the nature and origin of intoxication motives, considered firstly in relation to the organic constitution; secondly, to environmental conditions; and thirdly, to political, economic, and

social activities. The article is suggestive, but necessarily somewhat sketchy.

Revista de la Sociedad Medica Argentina.—Dr. Romulo Chiappori contributes to the current issue of this review an interesting paper on the pathology and inter-relations of the familial systemic degenerations of the nervous system, Friedreich's disease and the syndromes of Strümpell and Marie. The author strongly supports Raymond's view ("Pathologie Nerveuse," 1910) that these affections are not to be regarded as distinct entities, since they are but rarely found pure, patients suffering from any of these affections presenting, in the great majority of cases, both clinically and anatomo-pathologically, symptoms of more than one member of the group. An important feature of the paper is an elaborate and detailed study, histological and macroscopical, copiously illustrated by plates, of the lesions presented in the cerebrum, cerebellum, and upper part of the spinal cord in a case of spasmodic tetraplegia in a child of 4. An excellent bibliography accompanies the paper.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Remuneration of Asylums Medical Officers.

THE Metropolitan Asylums Board recently decided to increase the remuneration of assistant medical officers, giving as one of the reasons that the scale in the London County Council asylums service was higher than that of the Board. At the meeting of the London County Council on Oct. 28th, however, the Asylums Committee reported that it had adopted an increased scale of remuneration in respect of these positions. The committee stated that lately it had experienced great difficulty in securing the services of assistant medical officers, and it had become apparent that steps must be taken to improve and render more attractive the positions of the assistant medical staff in the London asylum service. The scale of remuneration for assistant medical officers had not provided hitherto an annual increment for any grade except the first. The fifth and sixth assistants received £170 a year each, the fourth £190 a year, the third £210 a year, and the second £250 a year in each case, with board, lodging, and washing, valued for superannuation purposes at £90 a year. The first assistant received a remuneration of £310 a year, rising by £25 a year to £410, with the same residential emoluments. The amended scale now adopted was as follows :—First assistant medical officer : commencing salary £350, rising by annual increments of £35 a year to £450. Second : £290, rising by annual increments of £10 a year to £330. Third £250, rising by £10 a year to £280. Fourth : £220, rising by £10 a year to £250. Fifth assistant medical officer, and all appointments under : £200, rising by annual increments of £10 to £220. The salaries included board, lodging, and washing in each case. The committee stated that the present expenditure on salaries for assistant medical officers amounted to £11,535 a year, and the amended scale involved an immediate increase of £1620, or just over 14 per cent.

Treatment of Uninsured Persons Suffering from Tuberculosis

When the Council adjourned the report of the Public Health Committee on the treatment of tuberculosis in London [1] had not been reached. The committee submitted a further report as to arrangements for the residential accommodation of uninsured persons. The committee remarked that as the result of legislation passed last session the position of the Metropolitan Asylums Board in relation to the provision of accommodation had materially altered, and, as already reported, the Local Government Board had expressed the opinion that the Council could now deal with the Asylums Board as with any other sanatorium-providing authority. In addition to accommodation which could be provided by the Metropolitan Asylums Board there was no doubt a number of beds at hospitals and sanatoriums available for London patients, and doubtless the existing accommodation, if found to be insufficient, would be augmented by the authorities concerned if they were satisfied that the Council would enter into arrangements with them for its use. The committee invited the Council to express the following opinion :—

That any comprehensive scheme for dealing with the treatment of tuberculosis in London shall provide that the Council shall make arrangements with the Metropolitan Asylums Board, with hospitals, and with sanatoria for the provision of the residential accommodation required for London uninsured patients suffering from tuberculosis ; and that it be referred to the Public Health Committee to consider and report whether adequate provision can be made in this manner without the Council being called upon itself to own and manage institutions.

To this Major LEVITA gave notice of an amendment expressing the opinion that the Council should not act as a financial intermediary between the Local Government Board and either the Insurance Committee or the borough councils, and should leave the local health authorities, together with the Metropolitan Asylums Board and other institution-providing bodies, to deal with the disease of tuberculosis under the same administration as at present dealt efficiently with other diseases.

Future of the Mount Vernon Hospital, Hampstead.

The London Insurance Committee wrote directing attention to the fact that the authorities of the Mount Vernon Hospital at Hampstead wished to dispose of the hospital, and suggesting that the institution should be secured if possible for the treatment of insured persons in London suffering from tuberculosis. The Public Health Committee advised the Council to decline to purchase the institution, and to direct the attention of the Metropolitan Asylums Board to its impending sale.

[1] THE LANCET, Oct. 25th, p. 1205.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on Oct. 30th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The PRESIDENT announced that Mr. Frank Caldicott had been elected twenty-first Jenks Scholar.

The following gentlemen having passed the required examination were admitted Members of the College : John Rupert Collins, M.D. Dub. (Cheltenham); Reginald Robert Elworthy, M.B. Lond., L.R.C.P. ; George Graham, M.D. Camb., L.R.C.P. ; John Athelstan Braxton Hicks, M.D. Lond., L.R.C.P. ; and Charles McMoran Wilson, M.D. Lond., L.R.C.P. (Hastings).

Licences to practise physic were granted to 105 gentlemen who had passed the necessary examinations.

The following communications were received : 1. From the Secretary of the Royal College of Surgeons of England, dated August 2nd and Oct. 13th, reporting proceedings of the Council of that College on July 31st and Oct. 9th respectively. 2. From the clerk of the Privy Council, dated Oct. 2nd, with enclosures relating to the International Health Bureau established at Jerusalem, and asking for observations upon the subject. After some discussion it was resolved that the substance of the communication and the correspondence in connexion therewith should be printed and distributed to the Fellows. 3. From Mrs. Edward Walker, of Wimbledon, dated Oct. 7th, offering for the acceptance of the College an original prescription of "Gregory's powder." The gift was accepted with thanks. 4. From Mrs. J. G. Curtis, of Chatham, Mass., U.S.A., dated Oct. 3rd, notifying that she has sent to the College, in accordance with the wish of her late husband, certain papers of the late Dr. Greenhill. The receipt of the papers was acknowledged with thanks.

A report was received from Dr. Aldren Turner upon the Third International Congress of Neurology and Psychiatry held in Ghent. The thanks of the College were given to Dr. Turner for his services. A report, dated Oct. 7th, was received from the Committee of Management. The Committee recommended that the Central London Ophthalmic Hospital should be recognised for the course of clinical instruction in ophthalmic surgery.

Dr. Frederick Taylor was re-elected a member of the Committee of Management.

After some further formal business the PRESIDENT dissolved the Comitia.

In the report of the Comitia held in July last it should have been announced that Dr. W. Rees Thomas, a Member of the College, had passed the additional examination (open to Members only) in Psychological Medicine. This was the first occasion that this examination had been held.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 8, 1913.

Research Work in Insanity and the Study of Curative Treatment of the Insane.

IF we read the signs of the times aright, British psychiatry is beginning to awake from its lethargy. Some 18 months ago we drew attention [1] to the unsatisfactory state of psychiatry in England, its comparative failure to advance notwithstanding the wealth of the material at its disposal, the obvious disadvantages under which the assistant medical officers of average asylums labour, and the absence of schools or clinics, except at one or two places, to attract the overseas visitor or to enlist the foreign graduate as a voluntary worker. But it is impossible for things to remain as they are once the interest of the profession is aroused. Those who have devoted and are devoting their best energies to the advancement of scientific psychiatry come in touch with kindred spirits from foreign schools, and their enthusiasm is bound sooner or later to exert a leavening influence on the great mass of latent energy that is to be found in our asylums and similar institutions, waiting for a suitable outlet to develop its powers. British psychiatry can no longer revolve in an eddying backwater while the current of scientific research is flowing strongly past it.

The problem to which we believe the psychiatrical expert is now thoroughly alive is, how to utilise for scientific and curative purposes the immense material at its disposal. An asylum should be as much a centre of research as a hospital: we all know that any self-respecting hospital will labour to keep itself well equipped and to render itself up to date, and the report which we publish this week by Dr. H. OSWALD SMITH, of the Standing Lunacy Committee of the Surrey county council, on the desirability of organising a research laboratory at Netherne Asylum, shows that similar efforts are being made by mental institutions. This is indeed a most welcome indication of advance. We are well aware that not a few asylums, county and otherwise, are provided with adequate laboratories and ample material, yet the output of clinical or pathological research is regrettably limited, almost entirely, we venture to think, because the incubus of routine work overwhelms the medical officers. Those who have lived and worked in large asylums know how appalling that routine may become. Dr. SMITH, in the case of Netherne Asylum, recommends that research work should be undertaken by a specially appointed officer, either a pathologist or a laboratory physician. The proportion of medical officers who are able to snatch time from their ordinary labours to devote to the prosecution of knowledge for its own sake is a small one, although, no doubt, opportunities are not wanting, but as at present constituted the daily programme of the medical officer of an average asylum is such as to render nugatory the efforts of many, even with the best intention in the world, to follow up lines of study and investigation which offer themselves to the observant physician. The proposal, therefore, is to appoint a special officer to work in coöperation with the medical staff, to perform duties more or less analogous to the clinical pathologist of the up-to-date hospital, to associate with the staff in the carrying out of modern lines of treatment rendered necessary by advance in our knowledge of syphilis, of diseases of the ductless glands, and so on. We are less concerned at this moment with the actual adjusting of the relations between such an officer and the residential medical staff; we should think the assistance thus provided and the atmosphere of research thus created are calculated to prove of the greatest value. What elicits our sympathy and our support is the determination of a responsible board to bring their institution demonstrably nearer that high level of attainment in curative research reached by the Crichton Royal Institution at Dumfries and by some other asylums in other parts of the country. The report is indicative of a freshening of spirit on the part of asylum authorities and of a healthy restlessness under present limitations which augurs well for the future.

Indeed, we see for a movement subjecting the material of our lunatic asylums to comprehensive and detailed research possibilities for great development. When the lessons learned in the laboratories of the psychiatrist are made available for the use not only of the pathologist but of the general biologist, the biometrician and the eugenist, it is certain that explanations may be forthcoming of problems which at present are perturbing the minds of many. Dr. CHARLES MERCIER, in his address upon heredity and inheritance as they concern the physician, delivered before the Society for the Study of Heredity and published in our columns this week, deals with several of those problems in a typically witty, whimsical, and dogmatic manner. With some of his criticisms we shall all be in accord, for he is a wise man and a master of his subject, while in other directions his following will not be so large; but a thoroughly scientific inquiry into the pathological condition of the inmates of our asylums cannot fail to clear away differences of opinion, if only by supplying firmer ground upon which to found opposing arguments.

[1] THE LANCET, April 6th, 1912.

The Extension of Plague.

IT is maintained by many authorities that an epidemic of human plague rarely occurs without an antecedent epizootic among rodents, generally the rat. Similarly it is contended that the endemicity of plague in certain well-defined regions is always associated with an enzootic, and that this occurs often among rodents of the marmot tribe, as, for example, in the tarbagan (arctomys bobac) in Mongolia and other parts of Central Asia, the suslik or spermophile (spermophilus guttatus) in the government of Astrachan in European Russia, and the ground squirrel (citellus beecheyi) in the State of California in North America. In each of these instances just mentioned the flesh of the animal is prized by the natives and eaten in a cooked or

uncooked condition. Cases are reported where plague has developed after the ingestion of such flesh; sometimes the hunter or trapper contracts the infection through an abrasion on his hand while skinning the animal. It is, however, probable that the most usual way in which plague is transmitted from the marmot to man is by the agency of the flea as it leaves the dead or dying animal to seek for a fresh host in man, failing another available marmot.

The history of plague shows that after a pandemic has ravaged the world the disease disappears, often for a long period, emerging again unexpectedly and spreading rapidly from east to west over the globe. Epidemiologists have long regarded China as the home of plague where the virus lies latent between the great pandemics; and history shows plague to be a disease of great antiquity in China. Recently it has been suggested that the conservation of the plague virus in China is due to the tarbagan, the haunts of which are far removed from those of man and the rat; so that long years may elapse before an accidental transference of the infection from the tarbagan to man takes place. So long as man keeps away from the tarbagan so long, it is maintained, plague remains latent; but when, as of late years, a demand for the fur of the tarbagan has arisen, Mongols, Buriats, Manchus, and even Cossacks are as a consequence recruited in considerable numbers to hunt and trap the animal on a large scale. It is evident that if plague existed among the tarbagan it is likely under such circumstances to be transferred on some occasions to the trapper in one of the ways indicated above. This is the generally accepted explanation of the origin of the terrible Manchurian epidemic of the winter of 1910–11. On the other hand, Dr. WU LIEN TEH (G. L. TUCK), director of the North Manchurian Plague Prevention Service,[1] contends that the rôle of the tarbagan in the spread of plague is not so important as some experts would have us believe. The Russian and Chinese Governments, however, seem to look upon the tarbagan as a source of danger, for during the last two years both Governments have prohibited the systematic hunting or trapping of this animal. The commission appointed by the Russian Government to investigate the cause of the continued endemicity of plague in the steppes of Astrachan found reasons for suspecting the suslik, or spermophile, of harbouring the disease. Although not yet sanctioned by the Government, plans are under consideration for the wholesale destruction of this marmot in Astrachan. It has been shown by experiment that infection of plague in this animal may be greatly prolonged, especially during the hibernating season. The population of that part of Astrachan where plague is endemic is sparse, and although year after year without exception plague appears among the nomadic tribes of this region, commonly in the pneumonic form, the outbreaks never attain large proportions, probably because the available human material gets exhausted in a short time. Nevertheless, the existence of this plague endemic area on the eastern borders of Europe is not without a certain amount of danger to the Western nations, with which, however, it has but little intercommunication.

In California there has existed for some years an enzootic of plague among the hordes of ground squirrels which infest the open plains of the great interior valley as well as the foot-hills and rocky canyons of that region. Sporadic cases of human plague occur from time to time within this area, the last instance being reported so recently as September. Inquiry invariably shows that the person attacked had been shooting, trapping, or otherwise handling ground squirrels on farms where infected animals had previously been discovered. This enzootic of plague has been found so far to extend to 12 of the Californian counties, Contra Costa and Alameda being the worst affected. To Passed Assistant-Surgeon GEORGE W. MCCOY, of the United States Public Health Service, we are indebted for much valuable information respecting plague in the ground squirrel. He has pointed out that in the vicinity of some Californian towns this animal and the rat may be found living in the same burrows. The flea usually present on the ground squirrel feeds readily upon the rat, and the rat flea is equally ready to feed on the ground squirrel. So that it would not be difficult for an infected ground squirrel to infect a rat through the flea and for this rat to carry the disease into a human habitation and communicate the infection to man. This danger is now generally recognised in California, and since 1908 a determined effort has been made to exterminate the ground squirrel, more particularly in the zones around the towns where the danger is regarded as being greatest. This animal, apart from plague, is regarded as a pest, for by its depredations on the crops it causes great losses annually to the farmer. Enzootic plague in California is a menace to the United States, since there is always the possibility of the actual transference of plague infection from these animals to man; and this, in conducing circumstances, might lead to a human epidemic of serious proportions. That the authorities are alive to the danger is evident, for the Californian State Board of Health has sent its secretary to Washington to confer with the Surgeon-General of the Public Health Service, and to invoke the assistance of the Federal Government in carrying out a campaign of "decitellisation," or extermination of the incriminated ground squirrels. All the evidence collected up to the present day points to the conclusion that the persistence of plague from year to year in a locality cannot be attributed to the conservation of the bacillus pestis in a free state outside the living body, but that the persistence is maintained exclusively by the passage of the virus from one living body to another. It may also be inferred that plague was originally a disease peculiar to rodents, and that its extension to the human species was in the first instance accidental.

[1] THE LANCET, August 23rd, 1913, p. 529.

The Housing Problem in Dublin.

THE leaders of the Labour party in their various speeches in perturbed Dublin during the bitter industrial dispute have said accurate and inaccurate things, shrewd and foolish things, but when any of them laid stress on the housing conditions to which the Dublin workman is subject he was sure of an attentive and sympathetic hearing, for it is well known that the Dublin housing conditions for the labouring classes are too often scandalous. The socio-political circumstances in Dublin have quieted down during the last few

days, but the insistence of the labour leaders on the importance of dealing with the housing question, following on the collapse of two tenement houses a few weeks ago, seems to have aroused the public conscience. Something is going to be done; one of the most pressing of municipal and sanitary problems in Ireland is, we hope, going to be tackled. It is at last felt by the community that the housing conditions of Dublin are not merely, as they have been for years past, a danger to the public health, but that they are becoming a menace to the social order.

The facts have, of course, long been known to all who cared to know them. In his official reports Sir CHARLES CAMERON, the medical officer of health of the city, has set them out year by year, when they form the regular text for leading articles in the daily press, where at other times the reflections by medical men and sanitarians upon the matter are regarded apparently as unnecessary jeremiads. Similarly, in his periodic charges to the city grand jury, the Recorder of Dublin, Mr. T. L. O'SHAUGHNESSY, has assigned to the housing conditions of the poor the origin of most of the crime which comes before him. Some of the facts given by Sir CHARLES CAMERON in his last annual report, that for 1912, which has been recently issued, are of such a nature that it is difficult to understand why popular outbursts and subsidence of structures have been necessary before the apathy of the authorities was overcome. The death-rate of the city was 22 per 1000 of the population, and the mortality under 1 year of age was 140 per 1000 births. These figures on their face only convey half their message. Both infant and adult mortality were specially high in the labouring class, so that in less than one-third of the community more than one-half of the deaths of children under 5 years occurred. The houses occupied by the workmen, the parents of these luckless children, are in many respects beautiful ones. They are, almost without exception, Georgian residences formerly occupied by the country gentry and professional families. Many of them are mansions of considerable beauty and size, and they have still the advantage that the rooms are large and lofty, and staircases and landings are spacious. These mansions are decayed to the ruin point, but they still display the virtues of their conception. Other houses are smaller and have little of either light or air, but in both the large and small houses the lettings are for a great part in single-room tenements. There are, in fact, 21,113 families, with a population of about 69,000, living in single-room tenements. That is to say, that over one-fourth of the population of Dublin live in such conditions. In Bristol, a city little larger than Dublin, the proportion of the population living in single-room tenements is only 1·5 per cent., and in Edinburgh, which historically and socially has many resemblances to Dublin, only 5·6 per cent. Needless to say, the death-rates in these cities are much lower than in Dublin. It requires little imagination to conjure up the picture of dirt and disorder to which such over-crowding as occurs in Dublin must conduce. The question of lavatory accommodation is but one of many, but the circumstances set out in this connexion by Sir CHARLES CAMERON may be taken as typical of the horrid whole. It is unusual, it appears, for these houses to contain any sanitary accommodation within the walls—not, perhaps, a matter of great complaint; but the only provision for a houseful of 30 or 40 people—men, women, and children—is too often one water-closet in the yard. It goes without saying that this water-closet, being used by six or eight families, is frequently in a filthy condition, and similar blindness to the ordinary rules of cleanliness can be witnessed in all the domestic circumstances of the Dublin lower classes. It is high time for reform.

It is not to be thought that no attention has been hitherto paid to the housing question in Dublin. Both the Dublin corporation and Lord IVEAGH have spent large sums in clearing some of the worst spaces and erecting healthy and sanitary dwellings. Unfortunately the rents required for these dwellings have put them beyond the reach of the labouring classes, and the tenants are artisans and clerks. Meantime, the clearance of the areas occupied by these new blocks has necessarily increased the congestion of surrounding areas, and the labouring classes, who constitute a large proportion of the working population, find themselves no better off. Under present economic conditions it seems impossible to provide housing for the working-classes at remunerative rents, and the problem is so urgent that improvement in economic conditions cannot be awaited indefinitely. The question is one, therefore, of capital expenditure either by the municipality or the State. The appointment of a Vice-Regal Commission to report as to the best means of procedure has been pressed, but when the Chief Secretary was approached he would not go further than to promise a departmental committee of the Local Government Board. As this body has been fully aware of all the circumstances for years, and has remained inert, little is expected from this proposal by the inhabitants of Dublin.

Annotations.

"Ne quid nimis."

THE PREVALENCE OF FATAL BURNS IN CHILDREN.

EVERY house surgeon and dresser knows how heavy is the toll in infant life, suffering, and deformity occasioned in children through accidents by fire. He also realises that although life may often be saved and suffering alleviated, the resulting disfigurement which in greater or less degree attends nearly all such accidents is permanent. It becomes, therefore, of the first importance that all investigations bearing upon the prevention of such accidents should receive careful consideration. In this connexion attention is called to the article on the mortality of children from burning, by Dr. W. A. Brend, which appears elsewhere in this issue, in which he classifies the deaths in children due to burning between 1906–1911, according to their ages, in boys and girls respectively. Dr. Brend, we think, makes out a good case for the view that the dress of girls is the predominant factor in the great disparity there shown to exist between them and boys as the subjects of such accidents, for this disparity begins to show itself only from the age at which the dress becomes differentiated in the sexes—i.e., about the third year, at which

time the ratio progressively decreases in boys, but continues to increase in girls until years of discretion are reached, and even then a decline occurs only very gradually. While the use of inflammable materials is no doubt partly to blame, Dr. Brend lays stress also on the fact that layers of such garments enclosing strata of air between them greatly increase the danger. The tendency to superimpose layers of garments on children is decreasing in these days and giving way to methods of dress more suited to bodily activity, but there are still many thousands of children, female children in particular, who are made into perambulating bundles by ignorant, well-meaning parents. A recognition of the part played by these layers of garments in relation to serious burns will doubtless tend to hasten their much-to-be-desired abolition. A totally different sort of burn is discussed by one of our Scottish correspondents, who points out, also in this week's issue, that a great many of the burns that occur in children in Aberdeen, according to the last report of the medical officer of health, were attributable to the application of poultices to relieve trouble in the chest or abdomen. It seems strange that such lack of ordinary judgment should obtain, but when we recall the fact that even nurses have been known to bathe patients in water that scalded them, one must not be too much surprised at a lack of discrimination in an untrained public. Both forms of injury have this in common—they point to the desirability of a general school training in at least the rudiments of physiology and hygiene.

MOUNTAIN SICKNESS IN THE ANDES.

FEW medical men have such opportunities of studying at first hand the symptoms of mountain sickness as those enjoyed by Dr. T. E. Ravenhill, who contributes a graphic account of this malady to the *Journal of Tropical Medicine and Hygiene* of Oct. 15th. For two years he acted as medical officer to a mining district in the Andes, situated at an altitude of over 15,000 feet above sea level. The railway brings passengers in 42 hours by fast train, in two days and a half if the journey be broken at Calamba, from Antofagasta on the Chilian coast to this high level. Arriving about midday the passenger complains of no symptoms until towards evening; then lassitude is felt, and he wakes up next morning with severe frontal headache, often with vomiting and with a rapid pulse. The tongue is furred and the eyes are dull and heavy, but the temperature is subnormal. A better day follows, and if the patient stays quiet the attack is soon over. To these symptoms, which are known to the natives as "puna," certain serious features may be added. If these are cardiac in type the patient presents the appearance of acute heart failure; the pulse is rapid and the heart-sounds feeble, there is cyanosis with intense dyspnœa, and if this condition is not treated by immediate return to a lower altitude death may follow quickly. It is curious that while perfectly healthy, robust persons may be attacked in this way, those who have cardiac disease are not specially afflicted. In the nervous type of puna delirium may be a prominent symptom, or there may be troublesome and persistent vertigo. In about 20 per cent. there is some epistaxis, but it is rarely profuse; occasionally blood is poured out from other mucous membranes. Puna is more frequently experienced by those who arrive in the mountains during the thundery weather which is common in the earlier part of the year; the best day for arrival is one characterised by clear, dry, cold weather. Those who take alcohol on the journey up suffer worse than those who do not; but travellers who expect to ascend the Andes may be consoled to hear that Dr. Ravenhill found that smoking does not aggravate the symptoms. Muscular work is apt to exaggerate the attack, and it is wise to keep quiet for a day or two after arrival Women seem to suffer less than men, and children less than adults. The aborigines do not suffer from puna as a rule. For the ordinary cases rest in bed with the window well open was sufficient to effect a cure. Aspirin was found to relieve the headache. Certain indigenous herbs, taken in the form of infusions, are supposed by the natives to have a curative action; this, however, Dr. Ravenhill's observations failed to confirm. He found the effect of oxygen inhalations disappointing. It appears that those who live for some time at high levels acquire a certain immunity to these symptoms, which lasts for a short time even if they return to low levels, but a sojourn of any duration quite destroys the beneficial effects of acclimatisation. On the other hand, the man who lives at the high levels feels fatigue more readily than one who has been living at ordinary altitudes and comes up thence to the mountains. The quicker the upward journey, the more intense the symptoms; and in certain valleys and other districts persons are inexplicably more liable to puna. A rapid descent to the lower altitudes is as a rule attended by little discomfort beyond headache and tinnitus. In conclusion, Dr. Ravenhill gives some interesting figures to show how rapidly the number of red blood corpuscles increases on arrival at high altitudes; in his own case they passed eight millions per cubic millimetre on the fifth day, and remained there or thereabouts indefinitely, and observations on other persons showed that this was an average experience.

VAGITUS UTERINUS.

VAGITUS uterinus is a very rare occurrence. Indeed, the reported cases have been received with considerable scepticism, and the arguments have been advanced that the sound heard was produced outside the uterine cavity and that air cannot gain access in sufficient quantity for respiration. In the *New York Medical Journal* of Oct. 11th Dr. J. H. Telfair has reported the following case which is unusually convincing, as the cries were heard by four practitioners. A woman, aged 24 years, was in her second labour at the Lying-in Hospital, New York. The first labour had been easy and the pelvic measurements were normal. After 38 hours she was exhausted and the cervix had dilated to the size of a silver dollar. As the fœtal heart was becoming weak and irregular it was decided to interfere. The cervix was soft and was manually dilated to the full extent in 20 minutes. The head was in the right occipito-posterior position and unengaged and the membranes were unruptured. Internal podalic version was performed, the membranes rupturing when version was half completed—i.e., when the long axis of the fœtus was at right angles to the uterus. At this time Dr. Telfair's right arm was in the uterus up to the elbow. The left leg was brought down to the vulva. He had just grasped the foot loosely preparatory to traction when his assistant flicked the sole with his finger. The plantar reflex was excited and the child gave a prolonged cry followed by two short, sharp cries. The cries sounded exactly as if the child were completely enveloped in a heavy blanket. Hurried extraction was performed, occupying less than a minute. The child breathed and cried normally without stimulation and showed no signs of having inspired more than the ordinary amount of mucus. It weighed 3560 grammes. Owing to the rapid delivery the cervix sustained severe bilateral laceration, which was repaired at once. The puerperium was uneventful. Three other members of the hospital staff (an attending physician and two of the house staff) were present and heard the cries distinctly. Dr. Telfair asks the question, Could a man of any experience mistake any other sound for the cry of a babe? In the criticism of the recorded cases the sound has been

attributed to a vibrating fold of membrane in the vagina, to the passage of gas per rectum, intestinal rumbling, and so on. For the production of vagitus uterinus two things are necessary: ruptured membranes and the presence of air in the uterus. In introducing the hands or instruments into the uterus it is difficult to exclude air. Air having once gained access, what is to prevent it filling all the interstices between the fœtus and the uterine wall? In normal labour after rupture of the membranes the head acts as a plug, and sufficient liquor amnii to fill the interstices between the fœtus and the uterine wall remains. During operative delivery the whole of the liquor amnii may drain away, and the interstices then become filled with air. The hand and arm of the accoucheur in the uterus, by further separating the uterine wall from the fœtus, enlarge the space not filled by the fœtus. Given air in the uterus one inspiration would be sufficient for a cry. There are two theories as to the cause of the commencement of normal respiration—the stimulus of air on the skin and the accumulation of carbonic acid in the blood in consequence of separation of the placenta. In the case recorded above stimulation of the skin seemed to be the cause, for the uterus did not appear to be sufficiently retracted to cause separation of the placenta. Moreover, the success of cutaneous stimulation of the newly born child when cessation of the placental circulation has failed is well known. Of 44 reported cases of vagitus uterinus more than half were operative deliveries, 11 being forceps, 15 versions, and one replacement of arm and cord. The fœtal mortality was 10 per cent. Dr. Telfair holds that once vagitus uterinus is heard the only hope of saving the child lies in rapid extraction, even at the expense of maternal lacerations. But unless the stimulus to inspiration be separation of the placenta, which he argues is not necessary, it is difficult to see why the child should be regarded as in so much danger.

WILSON AND WILSON v. MICHIE.

IN a probate action arising out of the will of Julia Beale Clout, a widow 49 years of age, a brother and sister of the deceased claimed to have the probate of her will and of a codicil, both made in 1912, revoked. By these the testatrix gave the whole of her property to Mr. J. Michie, who had been her medical attendant during the latter years of her life. By previous wills her relatives would have benefited. The plaintiffs alleged that the will and codicil had been made under the undue influence of the defendant, and also that at the time the deceased was of unsound mind and wanting in testamentary capacity. The solicitor who prepared the will and codicil in question, under which Mr. Michie was sole executor, gave evidence to the effect that he took his instructions from the testatrix in her own house, and that the defendant was not present either when the instructions were given or when the will and codicil were signed. He also stated that the testatrix was at the time of a sound disposing mind. This evidence, so far as it concerned the mental capacity of the deceased, and the absence of any appearance of influence exerted by the defendant, was corroborated by a servant and a nurse. The defendant also went into the witness box and gave a full account of his relations with the deceased, which, he stated, were those of a medical man towards his patient. There was evidence given of dislike evinced by the deceased towards her relatives. After the defendant's case on behalf of the will and codicil had been concluded the plaintiffs gave evidence, and witnesses were called on their behalf. The judge having summed up, the jury, without leaving the box, found that the will and codicil had been duly executed, that the deceased knew and approved of their contents, and that they had not been obtained by the undue influence of the defendant. Judgment was accordingly entered for the defendant with costs, Mr. Justice Bargrave Deane declining to allow costs out of the estate in the case of charges of using undue influence which had broken down.

ENTEROGENOUS MESENTERIC CYSTS.

A DEVELOPMENTAL anomaly which has received attention only in recent years is enterogenous mesenteric cysts. Their literature is almost entirely foreign; about 100 papers have been published since 1900. Enterogenous mesenteric cysts are of considerable surgical importance, but have probably never been diagnosed before operation or necropsy, and their mortality is about 35 per cent. In the *Johns Hopkins Hospital Bulletin* for October Dr. R. T. Miller has reported the following case. A female child, aged 4 days, was admitted into St. Francis Hospital, Pittsburgh, on Sept. 28th, 1912. She was the last of 13 children, all of whom, as well as the parents, were alive and well. Labour was normal. The child vomited everything taken, and the vomit was greenish-black. The bowels never acted, and there was no stain on the napkin. On examination she looked very ill. At intervals she cried in a thin weak voice as though suffering from paroxysms of pain. There was marked cyanosis of the face and hands. The skin was dry and wrinkled, especially over the extremities. The expression was pinched and drawn, and the limbs were little moved. The abdomen was not distended, and there was no visible peristalsis. Palpation caused the child to cry and was unsatisfactory. No mass could be felt or muscular spasm recognised. The abdomen generally was tympanitic, and there was no dulness in the flanks. The little finger could be inserted its full length into the rectum without encountering any obstruction. The rectal temperature was 97° F. Intestinal obstruction due to some unknown cause was diagnosed. Under chloroform a right rectus incision was made. On opening the peritoneum both dilated and collapsed cyanotic loops of small intestine were seen. In the right flank just below the level of the umbilicus a freely movable mass was found. This proved to be an oval intramesenteric tumour, about 4 cm. in its greatest diameter, and quite firm. Over the dome of the mass coursed a loop of small intestine which was flattened into a thin band by pressure. There was a volvulus of the mass and affected sector of the bowel of more than 180°, causing complete intestinal obstruction. The afferent bowel was greatly dilated and the efferent bowel collapsed. After reduction of the volvulus a circumferential area of pressure necrosis with a minute perforation was found. The patient's condition demanded haste, but a rapid enterostomy was not feasible as the obstruction was high in the jejunum. Resection and lateral anastomosis were hurriedly performed and the abdomen closed. Death occurred five hours after the operation. The tissue removed consisted of a loop of bowel 8 cm. long, within the mesentery of which was an egg-shaped mass measuring 4 by 3 cm. This was a cyst the wall of which was in part directly continuous with that of the jejunum. The cyst was lined with a layer of columnar epithelial cells bearing villi and resting upon a layer analogous to the submucosa, outside which were transverse and longitudinal layers of smooth muscular fibres. The structure of the cyst was thus exactly similar to that of the bowel, from which it had evidently been formed by sequestration during embryonic life. The adjacent portion of bowel was so stretched that its lumen was represented by a mere slit. In 1907 Niosi gave what appears to be the best classification of mesenteric cysts of embryonic origin, which is as follows. 1. Cysts of intestinal origin —(*a*) by sequestration from the bowel during development; and (*b*) from Meckel's diverticulum. 2. Dermoid

cysts. 3. Cysts arising from retroperitoneal organs (germinal epithelium, ovary, Wolffian body, Müllerian duct). The idea that a portion of an embryonic organ may become sequestrated and continue to develop, usually in an anomalous manner, is familiar. The lumen of the cyst constantly but slowly enlarges in consequence of retention of its own secretion. The actual process of sequestration from the developing gut was not observed until 1908, when Lewis and Thyng described the "regular occurrence of intestinal diverticula in embryos of the pig, rabbit, and man." These diverticula consist of downgrowths of the intestinal epithelium which may terminate in the muscular coat of the bowel or may extend quite through the bowel wall to form knob-like projections. They usually degenerate and disappear, but if one persists it may give rise to a mesenteric cyst. The surgical importance of mesenteric cysts lies in their liability to give rise to acute intestinal obstruction. The best treatment is enucleation when it can be done without seriously injuring or opening the bowel.

THE REGISTRATION OF PLUMBERS.

FROM a strictly medical standpoint the plumber is well deserving the attention he has received within recent times, but more is required to safeguard the public against possible evils likely to arise from incompetence or carelessness on the part of men engaged in plumber's work. Mr. W. D. Caroe, R.I.B.A., Master of the Worshipful Company of Plumbers, speaking at the Royal Technical College, Glasgow, impressed upon his audience that merely registering the men was not sufficient. Responsibility should be fixed on each man for the work he has executed, and this could only be done by every individual marking his work with his registered number. Mr. Caroe thought that every skilful man would be proud to identify himself with his work. The employment of registered plumbers would then stand as a guarantee of efficiency. It unfortunately happens that a great number, perhaps a majority, of those engaged in the plumbing trade are at present not registered, and have therefore no certificate to offer to the public in proof of their capacity for discharging efficiently and conscientiously the important work in which they are engaged, though doubtless many would experience no difficulty in passing the required tests. Mr. Caroe pointed out that the complexity of plumbers' work in modern times had so increased that it was more than a handicraft—he evidently considered it to be almost a branch of practical scientific work, and much can be said for the view. He urged, therefore, on educational authorities the need of providing technical instruction in harmony with the registration system, while the system of apprenticeship should be encouraged. To the men he pointed out that they should claim the privilege of their craft and qualify for registration, setting aside petty disputes and concentrating their attention on the lifting of a responsible handicraft to its merited position. All this we endorse. Unfortunately the bulk of the public, until some catastrophe happens through his carelessness or incompetence, regard the plumber and his work with little interest. The blame for any mischance which should rest upon their own lazy shoulders is shifted anywhere else. Properly qualified men can always be obtained for plumbing work if sufficient interest is exhibited by the employer in the way in which plans are executed, and registration is the obvious method by which a good supply of men can be kept up to the standard. If only this was kept in view every capable plumber would get himself registered, in order to be distinguished from the mass, some of whom may be ignorant or incompetent workmen. Under certain conditions the Plumbers' Company guarantee the work of their registered men. At present all registered men carry a card with their number on the register. It has been suggested that it would be desirable if each man wore a badge, the absence of which would put the public on their guard. This is the day of badges, and only the demand for registered plumbers will create the supply. The suggestion has practical force.

HEALTH OF THE POST OFFICE STAFF.

IN his annual report the Postmaster-General states that the health of the staff has again been satisfactory. The average sick-rate of the established staff during the year ended Dec. 31st, 1912, was 7·5 days for men and 10·9 days for women, and of the unestablished staff 4·6 days for men and 4·9 days for women. Seventy-five deaths and 111 retirements were due to diseases of tuberculous origin. The deaths recorded through the year showed an annual death-rate of 3·4 per 1000 for men and 1·3 for women on the established staff.

THE WILLIAM H. WELCH ENDOWMENT FOR CLINICAL RESEARCH.

THE magnificent gift by the General Education Board, founded by Mr. John D. Rockefeller, of $1,500,000, to provide professorial salaries in connexion with the Johns Hopkins Hospital and Medical School at Baltimore, marks an era in medical education. A professor of medicine, a professor of surgery, and a professor of pædiatrics are to be provided by the new endowment with salaries sufficiently high to make them independent of private work, and with a staff of assistants and laboratories, and are to devote themselves to scientific research in their respective departments. Dr. William Stewart Halsted, the present holder of the chair of surgery, has already accepted his chair under the new conditions. In view of the recent report upon the affairs of the University of London, the institution of these salaried professorships is of the first interest.

THE DIFFICULTIES OF DIAGNOSIS IN ANOMALOUS PLAGUE.

IN another part of our present issue we publish a very interesting and instructive communication by Dr. W. J. Tulloch, of Newcastle-on-Tyne, on the bacteriological diagnosis of plague, and in this he draws attention to the many difficulties which exist in recognising cases of plague which may arrive on our shores on healthy ships from foreign ports not known to be infected. Dr. Tulloch urges the examination by blood culture as a method to be adopted in all doubtful cases, and if used as a routine procedure in the indefinite febrile illnesses which occur on board ships it would, he contends, be found a valuable aid to diagnosis. The particular instance so carefully described by Dr. Tulloch occurred on a ship in the Tyne. The strain of the plague infection appears to have been peculiar, since two other cases of illness had previously occurred on the same vessel while it was lying in the Elbe and just before it sailed for the Tyne. The first case was diagnosed as influenza, but proved fatal on the third day; the second case had symptoms suggestive of enteric fever, the illness lasting 23 days before it terminated fatally. Post-mortem examination with bacteriological investigation of material ultimately established a diagnosis of plague in each case. The vessel in question with a cargo of grain, which is known to attract rats to the ship while it is loading, sailed for Hamburg from the Argentine port of Rosario, which has long been under suspicion in Europe of concealing the prevalence of plague in man and the rat in that place. The ship carried four apprentices, who occupied

a cabin at the stern of the vessel far removed from the quarters of the crew. The lads had a pet rabbit which was infested by fleas; it died while the ship was in the Elbe. It is conjectured that infected rats came on board at Rosario with the cargo; and that towards the end of the voyage the rabbit contracted the disease from the rats and conveyed it to three out of the four boys who were accustomed to play daily with their infected pet. The strain of infection, though peculiar in its manifestations, was nevertheless of a virulent kind, as all three apprentices died from it.

THE LONDON COUNTY COUNCIL AND THE TREATMENT OF TUBERCULOSIS.

THE London County Council, which has now apparently accepted the view of the Local Government Board that it, and it alone, should constitute the tuberculosis authority for the metropolis, is finding the preparation of a comprehensive scheme a task of much difficulty. For over a year the Public Health Committee of the Council has been engaged upon the problem of sanatorium benefit in London, and, as reported in our columns from time to time, the Council has had before it various recommendations. But the matter progresses slowly amidst the sharp differences of opinion, upon principle as well as detail, which are revealed in debate. London still lacks, even in outline, a coördinated scheme for dealing with its estimated 50,000 tuberculous inhabitants. At its last meeting on Nov. 4th the London County Council discussed the financial basis of that part of the Public Health Committee's report which concerns dispensary treatment of uninsured persons, and eventually some measure of agreement was reached. But the formulation and the carrying into early effect of a complete tuberculosis scheme for the metropolis are such pressing affairs that we may well ask all political parties within the Council to eschew recriminations and keep strictly to the business in hand.

THE IODINE CONTENT OF FISH THYROIDS.

THE observation that a fish diet increased the iodine content of a dog's thyroid was made some time ago. The constant presence of iodine in sea water has suggested that the thyroid of salt-water fishes might contain a relatively large amount of iodine. If iodine is present in sea water as suggested by Gautier in organic combination it is probable that the iodo-organic compound is capable of assimilation and transmission. It now appears from an interesting note upon this subject by Mr. Alexander T. Cameron, published in the October number of the *Biochemical Journal*, that definite evidence has been obtained that unusually large amounts of iodine are constantly present in some species, a finding which lends some support to the view that the iodine content of the thyroid is a function of iodine in the diet. In the specimens of fishes selected for analysis the thyroid of the raia clavata was found to contain amounts which were not extraordinary compared with that found in the thyroid of the mammals, but the thyroid of scyllium canicula contained more, and in one case much more, iodine than any thyroid previously reported upon. Thus, accepting the following figures for the dog as 0·692 per cent. on dried gland, 0·588 per cent. for the human gland, 0·531 per cent. for the gland of the pig, 0·53 per cent. for the gland of the sheep, and 0·477 for the gland of the ox, the fish thyroid referred to contained as much as 1·160 per cent. of iodine. This is, of course, a very remarkable amount, and further investigations in this direction will be looked forward to with interest. The research, so far, suggests that fish thyroid would be a valuable therapeutic agent, and would appear to add strength to the view that the iodine value of the diet plays a considerable rôle in determining that of the gland.

SIR RICKMAN GODLEE'S VISIT TO THE UNITED STATES AND CANADA.

Sir Rickman Godlee, President of the Royal College of Surgeons of England, accompanied by Lady Godlee, left at the end of October for Chicago, where he is to give an address at the first congregation of the American College of Surgeons and admit the Fellows of the new college. The address will take the form of a historical sketch of the English College of Surgeons, and will detail the circumstances in which the order of Fellows came into being. Sir Rickman Godlee hopes to avail himself of an invitation to visit Toronto, where a number of Fellows and Members of the English College are resident.

THE GENERAL MEDICAL COUNCIL.

THE next session of the General Council of Medical Education and Registration is announced to begin on Tuesday, Nov. 25th. The illness of the President, Sir Donald MacAlister, has now taken a favourable turn, but he will be unable to attend the Council. A chairman will be elected for the forthcoming session, a precedent for which proceeding occurred during the illness of Sir Richard Quain in the autumn of 1897. There will be no change in the plans for the forthcoming session.

Sir Thomas Oliver will deliver a course of six lectures on "Industrial Hygiene" at the Royal Institute of Public Health, the first two of which will be given on Wednesday and Thursday, Nov. 12th and 13th, at 5 P.M.

THE King has approved the appointment of Surgeon-General Arthur Thomas Sloggett, Director of Medical Services in India, to the post of Director-General of the Army Medical Service, in succession to Surgeon-General Sir W. Launcelot Gubbins, whose term of office will shortly expire.

A SPECIAL meeting of the Representative Body of the British Medical Association has been summoned for Thursday, Dec. 4th, and if necessary Friday, Dec. 5th, at the Connaught Rooms, Great Queen-street, London, W.C. The business before the meeting includes the proposal to raise the annual subscription to 2 guineas; the alternative schemes of the State Sickness Insurance Committee and the National Insurance Act Committee for the establishment of a special fund for professional organisation; and the Council's report on various matters relating to the National Insurance Act.

THE King, acting on the recommendation of the Home Secretary, has appointed the following to be paid Commissioners under the Mental Deficiency Act, 1913: Sir William Byrne, Dr. Arthur Rotherham (medical superintendent of Darenth Asylum), and Miss Mary Dendy. The four unpaid Commissioners have yet to be appointed. The new Board of Control under the Act consists of Sir William Byrne (chairman), Dr. Rotherham, Miss Dendy, and Mr. B. T. Hodgson (secretary to the Board of Commissioners in Lunacy), together with Dr. C. Hubert Bond, Dr. Frederick Needham, Dr. E. M. Cooke, Dr. Sidney Coupland, Mr. L. L. Shadwell, Mr. A. H. Trevor, and Mr. S. J. F. Macleod, K.C. (Commissioners in Lunacy).

RESEARCH WORK IN INSANITY AND THE STUDY OF CURATIVE TREATMENT OF THE INSANE.[1]

BY H. OSWALD SMITH, M.B., CH.B. EDIN.,

MEMBER OF THE STANDING LUNACY COMMITTEE OF THE SURREY COUNTY COUNCIL; MEMBER OF THE NETHERNE VISITING LUNACY COMMITTEE, CURATIVE RESEARCH, AND MENTAL DEFICIENCY COMMITTEES.

A Report to Establish and Organise a Research Laboratory at Netherne Asylum.

THIS report is based on methods adopted by several of the large asylums, at the heads of which are medical men who have advanced psychiatry to a much more hopeful position, and whose efforts are still being maintained along these channels of research whereby new methods of treatment are evolved for the benefit of the mentally afflicted.

An asylum ought not to be merely a place where patients are well cared for and housed, but must have a definite plan so that research work is undertaken by a specially appointed officer who is enthusiastic about his work and efficient in the present-day technique of research work in psychiatry. He should have the proper facilities in a well-equipped laboratory for laboratory diagnosis and study. There must, however, be coöperation between this officer and the resident staff in the work. The primary duty of the resident staff is —(1) the proper examination, (2) treatment, and (3) care of the patients. This work provides infinite lines for study and research for the medical staff, provided always that their primary duties do not take up their whole time. It is well known that certain men who are interested in research work will make time for such extra duties; thus they keep abreast of medical progress and form their own judgment as to the permanent value of the latest advances and ideas.

There are many lines of a clinical and therapeutical nature that can be most appropriately followed out by the ordinary staff. At the same time it is of the greatest advantage to county asylums, such as Netherne, that a fairly equipped laboratory should be regarded as essential. If the ordinary medical staff find that their time is so fully taken up with the ordinary work in the wards that they have not time or that they have not the necessary technical training to do laboratory work—as to the amount of medical work in an asylum the annual admission rate gives a fair indication of the amount of work to be undertaken—a pathologist should be provided at a salary of not less than £250 a year to begin with, in order to get a really good and efficient man, because the ultimate research work would rest largely in his hands. If the assistant medical officers have time to follow up a clinical and therapeutical research, then such an appointment would bear good results, but if the medical staff have not the necessary time, then instead of a pathologist the appointment of a laboratory physician might be made at an initial salary of £250 a year.

This physician could have the laboratory fitted up according to his special requirements, and such sum as £250 as a preliminary outlay would be sufficient. It is only after years of time, thought, and expenditure of money that curative research has reached the high-water mark obtained in such asylums as the Lancashire County Asylum at Prestwich, the Crichton Royal Institution, and the Edinburgh Royal Asylum. The knowledge of curative research is added to slowly, but if such a scheme as the above is adopted at Netherne the committee will have the benefit of the research work of these asylums and the practical results. When Netherne earns such a report from the Commissioners in Lunacy as the Crichton Royal Institution did for 1912, then, and not till then, shall we be able to say that the patients at Netherne are receiving the most appropriate treatment. If the total expenditure on research work be divided by the average amount of patients under treatment a year it will be found that the general cost per caput per annum for the purposes of laboratory diagnosis, study, and research is not a fraction of the cost of each patient's keep, and such expenditure would be well worth it.

Estimate (apart from cost of building) of initial expenditure for the purpose of promoting curative research work at Netherne.

Pathologist at a salary of £250 a year, with residence; or at a salary of £300 a year living outside.

A further sum of £250 for initial expenditure in fitting up a laboratory.

The above scheme presupposes the coöperation of the resident medica staff along the lines of clinical and therapeutical treatment.

Failing this coöperation in the meanwhile the appointment of a—

Laboratory physician at an initial salary of £250 a year, with residence; or £300 a year outside.

A sum or £250 for initial expenditure in fitting up a laboratory.

Forms of application for the above post, whichever is decided upon, can be subsequently drawn up so as to get the best candidates.

Organotherapy.

The second part of this report deals with organotherapy and the open-air treatment of the active insane by rest in bed. The committee must look to the resident medical staff to carry out this part of the work. In psychiatry and neurology great advances have been made, and these are due to the whole-hearted efforts of men who have ever kept the flag of research flying. There opens out the vista of organotherapy, and by this is meant the employment of certain glandular extracts in the treatment of insanity. Thyroid extract, cerebral extract, mammary, pancreatic, ovarian, pituitary and orchitic extracts, these are some which have been used and experimented with by psychiatrists. It is known that causes of cretinism can be combated by the use of thyroid, and Brown-Séquard maintained that he had "rejuvenated" himself by orchitic extract. Myxœdema, due to the absence of the thyroid gland, can be cured by the administration of thyroid extract. Cerebral extract is found to promote the appetite, and is a good tonic to the general nervous system. These are some examples of the research work placed at the disposal of humanity and obtained by means of work in the laboratory. The committee should expect coöperative research to be based on these lines, which should also embrace the bacteriological examination of the blood and cerebro-spinal fluid, the conditions of which have an important bearing on general paralysis of the insane. The use of vaccines and antisera would have to be investigated.

Administrative duties have become so heavy that it is impossible in many cases for the medical superintendent to give much attention to clinical work, and so we must expect the assistant medical officers who have adopted lunacy service as a specialty to be properly trained in up-to-date knowledge of the treatment of the insane. Post-graduate courses are provided in connexion with most of the universities.

Open-air Treatment by Rest in Bed.

And finally there must be placed on record an estimate of a form of treatment of the insane from which there is expected brilliant results. It is the open-air treatment of the active insane by rest in bed. This treatment can be carried out by the staff without undue strain on their time and little additional expenditure of money. It has been carried out with great success at Ayr Asylum with a resulting increase in the recovery rate. Verandahs are used on the male and female sides. Separate beds with wooden partitions are placed on these verandahs. (Details of the scheme can be supplied.)

What are the effects of rest in bed in the open air in the case of newly admitted and actively insane patients, and wherein do the effects of outdoor rest in bed differ from those of outdoor exercise and indoor rest? First and foremost, there is a rapid subsidence of the active mental and nervous symptoms, there is a rapid amelioration of mania, melancholia, delirium, vivid hallucinatory and delusional manifestations, of restlessness and excitement of all kinds and insomnia. The general effect is that the large majority of newly admitted patients show distinct improvement of various morbid mental states, become less restless, more manageable, and more contented, and regain their sleep with greater rapidity than with any other known method. Secondly, there is a rapid improvement in the physical condition, a noticeable improvement in the condition of the skin, the appetite improves, and the majority readily take their food and do not require to be spoon-fed as is usual with new patients; a distinct improvement in the state of the tongue and gastric digestion if previously impaired. Hypnotics, sedatives, and laxatives can under this treatment be dispensed with. The increase in the body weight is 5 lb., 6lb., or 7 lb. during the first two or

[1] Being a report to establish and organise a research laboratory at Netherne Asylum, with remarks upon the open-air treatment of the insane and organic therapy treatment. The report was adopted by the Standing Lunacy Committee of the Surrey county council on July 7th, 1913.

three weeks on simple diet, consisting largely of milk and milk-puddings.

Similar treatment can be adopted in the cases of all residents of shorter or longer standing, exhibiting relapses or phases of active insanity, including the most difficult and dangerous cases in the asylum. The wooden partitions already alluded to add the valuable feature of isolation to the treatment. The recovery rate is remarkably influenced by this treatment. From the description of the open-air treatment of the insane it will be at once seen that the combination of rest in bed with open-air treatment secures the natural rest to the nervous system and gives the patients in their initial treatment a good chance of recovery; the cost in mere money would be very little in comparison to the benefits. It is a pleasant remedy, both to those who receive the treatment and those who administer it. In placing these points before you, I wish to acknowledge the assistance I have received from many of the leading psychiatrists, who have willingly placed their knowledge at my disposal for the benefit of the committee. I have had the privilege of reading many of the special papers published in the medical journals. The length of the report is owing to the difficulties of the subject which has been too inadequately handled by me.

The Recovery Rate and the Cost of the Schemes.

The recovery rate for 1912 on all admissions into the Crichton Royal Institute was 35·5 per cent.; the Edinburgh Royal Asylum 36·0 per cent. In both these institutions research work is diligently carried on. The recovery rate on all admissions into Netherne Asylum for 1909 to 1912 was 12·0 per cent.; Brookwood Asylum for 4½ years, 24·6 per cent. In future the annual recovery rate should be placed on record, so that a just and fair comparative result may be available.

It is therefore necessary to deal with curative research at Netherne Asylum from the practical point of view so far as cost is concerned. Dr. S. N. Crowther, senior medical officer of Netherne, has worked out the cost of a scheme which includes buildings, fittings, salaries, and upkeep. This scheme embraces the cost of open-air treatment of the insane by rest in bed and the proper grading of the insane.

Summary of annual cost per head per week.—(1) Curative research, 2·51*d.*; (2) open-air treatment, 1·35*d.*; (3) grading of patients, 4·03*d.*—total cost of three schemes, 7·89*d.* This includes salary of a pathologist and neurologist at £350 per annum.

Summary of initial and non-recurring expenditure.—Laboratory, £360; fittings and apparatus, £200; three verandahs (12 beds in each), £765—total cost of the three schemes, £1325.

The Grading of Patients.

The attention to the proper grading of patients in all asylums is called for. Asylum patients may be divided into two main classes—(1) curable and (2) incurable; and while for those of the first class every means known to science should be used to facilitate recovery, the treatment of the second class is not so important, and the present method of grading is on the whole satisfactory. It is mainly the extra cost which has hitherto deterred the asylum authorities from proper grading of patients. It was usual to distribute a certain number of noisy and excited patients among those who were miserable and depressed, with the hope that an interaction might take place to the mutual benefit of the patients concerned. Such methods must be relegated to the background, and it is only by progressive and enlightened treatment, stimulated by research, that psychiatry shall take the long-awaited step forward.

I wish to thank Dr. Crowther for his help and valuable suggestions in the preparation of my paper.

ROYAL ARMY MEDICAL COLLEGE.

ON Oct. 29th a distribution of prizes by Surgeon-General Sir HAVELOCK CHARLES, G.C.V.O., took place at the Royal Army Medical College. A large company assembled to do honour to the occasion, among them being Surgeon-Generals W. Donovan, Sir David Bruce, G. J. H. Evatt, H. R. Whitehead, W. H. Macnamara, Sir Francis Trevor, and Sir Charles Cuffe, A. W. May (Director-General of the Medical Department, Royal Navy), Sir James Porter, Sir A. Bradshaw, and many others, including Major Sir Ronald Ross, Lieutenant-Colonel P. J. Freyer, Dr. James Galloway, Mr. A. E. J. Barker, and Dr. F. W. Mott.

Surgeon-General W. BABTIE, V.C., C.B., C.M.G., Deputy Director-General, opened the proceedings by calling upon the Commandant to read his report.

Colonel BRUCE M. SKINNER, M.V.O. (Commandant), reviewed the session, the 106th of the junior class of the College, being also the twenty-third held in London. After referring to the Seventeenth International Congress of Medicine, the Naval and Military Section of which held its meetings at the College, he said there had been some changes in the staff. While regretting the completion of tenure of their appointments, they of the College wished God-speed to Major W. S. Harrison, lately professor of tropical medicine, and to Major J. C. Kennedy, assistant professor of pathology, with the hope that their talents so long devoted to this College might find fields fruitful of discovery awaiting the application of their highly trained energies. On the other hand, they welcomed their successors, Lieutenant-Colonel O. L. Robinson in the chair of tropical medicine, and Major S. L. Cummins as assistant professor of pathology. With regard to the class now being closed he reminded those present that they were fully qualified doctors before passing into the College, where they had been instructed in matters relating especially to the preservation of health and physical well-being of the soldier. He had nothing but praise for the young officers who composed this class, for they had been most assiduous and attentive, while those who had gained prizes had done remarkably well, and in two cases brilliantly, for instance, the winner of the Fayrer and the Marshall Webb medals had gained over 90 per cent. of marks in those competitions. He then read the names of those who had gained prizes, as well as those who came second, as follows:—

	Marks.
1st. The Herbert Prize (highest total of marks): Lieutenant R. B. Price, R.A.M.C.	565/700
Proxime accessit: Lieutenant H. C. D. Rankin, R.A.M.C.	536/700
Hygiene.	
1st. Parkes Memorial: Lieutenant R. B. Price, R.A.M.C.	153/200
Proxime accessit: Lieutenant A. K. Sinha, I.M.S.	151/200
2nd. De Chaumont: Lieutenant A. L. Urquhart, R.A.M.C.	144/200
Proxime accessit: Lieutenant H. C. D. Rankin, R.A.M.C.	142/200
Pathology.	
1st. Fayrer Prize: Lieutenant S. S. Sokhey, I.M.S.	181/200
Proxime accessit: Lieutenant N. M. Mehta, I.M.S.	160/200
2nd. Tulloch Memorial: Lieutenant R. B. Price, R.A.M.C.	168/200
Proxime accessit: Lieutenant A. L. Urquhart, R.A.M.C.	164/200
Surgery.	
1st. Montefiore: Lieutenant A. Seddon, I.M.S.	80/100
2nd. Montefiore: Lieutenant H. C. D. Rankin, R.A.M.C.	75/100
Tropical Medicine.	
1st. Ranald Martin Gold Medal: Lieutenant A. K. Sinha, I.M.S.	86/100
Proxime accessit: Lieutenant R. B. Price, R.A.M.C.	84/100
Administration.	
1st. Marshall Webb Prize: Lieutenant H. C. D. Rankin, R.A.M.C.	97/100
Proxime accessit: Lieutenant R. B. Price, R.A.M.C.	88/100

Sir HAVELOCK CHARLES next distributed the prizes with a few appropriate words to each recipient, and in his address which followed advised and encouraged the young officers as to their course in life, directing his remarks more particularly to those whose careers would lie in India. He said it was often asked why in life the race was not always to the swift nor the battle to the strong; the reason was that some men had not the tact and judgment to avail themselves of the chance when it offered. They failed through lack of character. The greatest of all assets was character. He was present at a similar meeting to this 31 years ago, and though he could not recall that any address was given on that occasion, he remembered that on his way up to town he travelled with Sir Joseph Fayrer, whose advice he asked as to how to get on in India. After looking at him for a few seconds Sir Joseph Fayrer said: "Do what you are told; don't grumble; go where you are ordered." Of course, young men going to India would have troubles like everyone else, like the panel doctor as well as the medical man in Harley-street; but they should remember Sir Joseph Fayrer's advice; and, further, they should strive to prove themselves thoroughly reliable—a most valuable characteristic for every officer. They were going to what he considered the most interesting country in the world. He wished them the best of good luck in the words of the Persian poet who said: "May the sweet waters of contentment spring up where'er you place your feet."

Surgeon-General BABTIE thanked the General Officer

commanding the London District for the interest he had shown in the Corps by his presence on this occasion, and called for a vote of thanks to Sir Havelock Charles, which was given by acclamation.

General Sir FRANCIS LLOYD, K.C.B., C.V.O., D.S.O., commanding the London District, thanked the Deputy Director-General for giving him the opportunity of letting the company know his appreciation of the work done by the Royal Army Medical Corps, and spoke in sympathetic terms upon the cordial relations springing up between them and the rest of the army.

The proceedings then closed, and the company adjourned to the mess where the officers of the Corps were "At Home."

SOME EXPERIMENTS WITH CLINICAL THERMOMETERS.

THERMOMETRIC observations in clinical practice are, of course, of the greatest importance, but the thermometer must be accurate, as unless that is the case a very serious error in diagnosis may obviously arise. Now and again the accuracy of the clinical thermometer has been impugned, but the clinical thermometers supplied by well-known instrument makers are on the whole generally trusted. It would be a counsel of perfection to lay down that every observer should see for himself that the thermometers he uses are correct recorders of temperature. In practice that is seldom done.

Nor is the offer of certification made by the authorities at the physical laboratories at Kew universally accepted. In private practice it may be, but in hospital practice probably not at all, as it adds considerably to the cost of the instrument, the fee for testing being 1*s.* for each thermometer. In THE LANCET of Oct. 4th, 1913, we published a letter from a correspondent in which he issued a warning as to the unreliability of low-priced clinical thermometers, and he recorded the results of some tests he had made with thermometers supplied by a well-known firm of surgical instrument makers at the price of 10*s.* 6*d.* per dozen. In many instances the readings compared with Kew tested thermometers were far from accurate, and the divergence was such as to render the instruments misleading, indeed valueless, for diagnostic purposes. The finding was undoubtedly a serious one, and our correspondent did good service in drawing attention to the matter. On the other hand, his results were criticised in a letter from another correspondent which appeared in THE LANCET of Oct. 11th, 1913, who regarded the variations described as not necessarily indications of faulty instruments. It is possible, he stated, to immerse a dozen quite reliable instruments in warm water and obtain as many different readings. In performing the test he pointed out that the precautions which must be observed are that the thermometers should be well "shaken down" before they are tested, that the water should be maintained at a constant temperature, and that the instruments should not touch the bottom or sides of the vessel in which they are tested." We must agree that these precautions are very reasonable when we compare what may be called the artificial method of testing with the conditions under which the body temperature is taken. Their observance, at any rate, has the merit of scientific method and shows, according to our second correspondent's experience, that the percentage rejections of clinical thermometers supplied to the hospital to which he is attached, which "is very small indeed," has reason behind it.

We have recently made a number of tests with clinical thermometers on these lines, and so far our experience agrees with the more favourable view expressed in our columns, but with one important limitation. We obtained thermometers from several well-known instrument makers, the charges for them being from 1*s.* 6*d.* to 2*s.* 6*d.* a piece, not, be it observed, 10*s.* 6*d.* per dozen. They were bought in the ordinary way, no information passing as to the special purpose for which they were required. The thermometers were marked "30 secs.," indicating that they were adjusted for making short-time observations. We considered it of interest to test these after 30 seconds' immersion in a bath of water at various temperatures chosen to represent the human range, and to repeat the trials keeping the thermometers immersed for two minutes. The results are recorded in the following tables, the temperatures, as shown by a standard thermometer used for scientific purposes in the chemical laboratory and ascertained to be accurate, being respectively 95·3° F., 98° F., 100·3° F., 105·3° F.

TABLE I.—*Immersion Temperature 95·3° F.*

	½-minute readings.	2-minute readings.		½-minute readings.	2-minute readings.
1—1*s.* 6*d.*	104·9	105·5	1—1*s.* 9*d.*	105·0	105·2
2—1*s.* 6*d.*	104·6	105·0	2—1*s.* 9*d.*	104·9	105·3
3—1*s.* 6*d.*	104·7	105·0	3—1*s.* 9*d.*	104·2	105·3
1—2*s.* 6*d.*	105·2	105·1	1—1*s.* 6*d.*	104 8	105·6
2—2*s.* 6*d.*	105·2	105·0	2—1*s.* 6*d.*	104·7	105·6
3—2*s.* 6*d.*	105·2	105·1	3—1*s.* 6*d.*	104·9	105·5

On the whole, the results show that for practical clinical purposes the thermometers gave fairly accurate readings. It is interesting to note, however, that at the temperatures

of 100·3° F. and 105·3° F. the readings in many instances were closer to the actual truth as shown by the standard thermometer when two minutes observations were made. The lesson of this appears to be that for quite accurate readings it would be better to leave the half-minute thermometer in position for two minutes rather than half a minute.

"The fashion of the day," writes a correspondent to us this week, "sets towards 'half-minute' thermometers; the old-fashioned massive type which required five minutes incubation has been practically ousted from the market. A great many of these so-called 'half-minute' thermometers do not really give true readings in that short space of time, though they may be perfectly reliable after longer incubation." This view receives confirmation in the experiments we have undertaken, and our correspondent records some observations which prove the truth of his statement.

On the other hand, a thermometer may read too high if left too long, as the following observation shows. The temperature of the water was 100·3° F. according to the standard thermometer; a clinical thermometer (half-minute observation) gave exactly 100° F. on a half-minute observation, but the reading was 100·8° F., after five minutes observation. It will be noted also that certain of the thermometers failed to record as low as 95° F. after 30 seconds, which is probably not important so long as they recorded accurately above this point. With a two minutes immersion the mercury column reached the point.

It is stated also that the accuracy of a thermometer may be impaired by using it after it has been exposed to the cold. The following table shows that with the particular thermometers tested their accuracy of recording was not seriously affected after they had been exposed to temperatures respectively of 40° F. and 50° F.

TABLE V.—*Test of Thermometers left in the Cold (40° F. (1) and 50° F. (2)).*

Thermometers and prices.	Temperature shown by standard thermometer, 100·3° F. ½-minute readings.		Thermometers and prices.	Temperature shown by standard thermometer, 100·3° F. ½-minute readings.	
	(1)	(2)		(1)	(21
1—1*s.* 6*d.*	100·1	100·2	1—1*s.* 9*d.*	99·9	100·0
2—1*s.* 6*d.*	99·9	99·9	2—1*s.* 9*d.*	99·6	100·2
3—1*s.* 6*d.*	100·0	100·1	3—1*s.* 9*d.*	Broken.	—
1—2*s.* 6*d.*	99·9	99·9	1—1*s.* 6*d.*	100·2	100·2
2—2*s.* 6*d.*	99·8	99·8	2—1*s.* 6*d.*	100·0	100·1
3—2*s.* 6*d.*	99·8	99·9	3—1*s.* 6*d.*	100·0	100·1

In regard to the importance already referred to of shaking the column of mercury right down as far as it will go before making an observation, the following results are of interest. The thermometers here showed a starting point of 97° F. In other words, they were not completely shaken down.

TABLE VI.—*Starting Point of Thermometers 97° F.*

Thermometers and prices.	Temperature shown by standard thermometer, 100·3° F. ½-minute reading.	2-minute readings.	Thermometers and prices.	Temperature shown by standard thermometer, 100·3° F. ½-minute reading.	2-minute readings.
1—1*s.* 6*d.*	100·2	100·3	1—1*s.* 9*d.*	100·4	100·4
2—1*s.* 6*d.*	Broken.	—	2—1*s.* 9*d.*	100·4	100·4
3—1*s.* 6*d.*	100·3	100·3	3—1*s.* 9*d.*	Broken.	—
1—2*s.* 6*d.*	100·0	100·0	1—1*s.* 6*d.*	100·1	100·1
2—2*s.* 6*d.*	100·0	100·0	2—1*s.* 6*d.*	100·3	100·3
3—2*s.* 6*d.*	100·3	100·3	3—1*s.* 6*d.*	100·3	100·0

According to these results the omission to "shake down" the column below 97° F. before making an observation did not appear to impair the accuracy of the record. For really accurate observations, however, the 30 seconds thermometers give, generally speaking, more satisfactory results when they are incubated for more than 30 seconds, and according to the above experiments an incubation of a period of two minutes records the practical truth.

So far the results show no startling discrepancy, but the inquiry is by no means complete. We hope to publish the results of a similar series of experiments made with cheap instruments. In the meantime it is pleasing to record that the instruments procured from certain well-known makers have proved reliable for all practical purposes.

METROPOLITAN ASYLUMS BOARD.

Proposed Increased Remuneration of Assistant Medical Officers.

THE Metropolitan Asylums Board on Nov. 1st considered proposals in connexion with the salaries assigned to assistant medical officers in the Asylums service. The Asylums and Finance Committees referred to the difficulty which for some time past had been experienced in obtaining assistant medical officers. This experience was not confined to the Board, but was general throughout the country, and was due in part to fewer entries at the medical schools and, to a greater extent, to recent legislation, which had opened out a wider field of employment to medical men. While there had been a general increase in the salaries offered to assistant medical officers in asylums throughout London and the country the Board's rates of remuneration compared unfavourably with those prevailing in the London County Council and Home Counties asylums. It was proposed that the scale of remuneration of these officers should be increased, and the following table showed the present rates paid and the revised rates suggested:—

Grade of assistant medical officer.	Present scale.			Proposed scale.		
	£	£	£	£	£	£
Senior	250 ...	10 ...	300	300 ...	15 ...	360
Second	180 ...	10 ...	200	210 ...	10 ...	250
Third and fourth...	150 ...	10 ...	170	180 ...	10 ...	200

Note.—All with the emoluments of board, lodging, and washing. The increments are annual ones.

The Finance Committee concurred in the proposals on the understanding that the increased remuneration would cover any extra services that might be rendered under the National Insurance Act (services which were light and, in the asylums, would be a diminishing quantity).

The Board decided to make the increases in the scale of remuneration.

The Principal Medical Officer of the Board.

The General Purposes Committee reported that it had received an application from Dr. H. E. Cuff, the medical officer for general purposes, for a reconsideration of his position and the salary attached thereto.

Dr. Cuff was appointed under the designation of medical officer for general purposes in February, 1908, and since that date had been remunerated at the rate of £850 per annum. Over five years having now elapsed the committee thought it desirable to review Dr. Cuff's position on the Board's staff and the duties and responsibilities attached to his position. There could be no doubt that these had materially increased since the appointment was made. Dr. Cuff now took part in every branch of the Board's work, and was called upon to advise upon reports and requests received from all sources, including those from outside authorities, as well as those made to committees and subcommittees of the Board. His work covered important questions of institution administration, of arrangements of accommodation, and of treatment of diseases, including those dealt with by the Board and those which it was suggested should be received for treatment. The committee was of opinion that the position which Dr. Cuff in fact occupied of principal medical adviser to the Board was very indistinctly recognised by his existing title, and that it would be in the Board's interest to attach to the post a designation which would strengthen Dr. Cuff's position and attach more significance and weight to his reports, many of which the Board found it desirable to issue to other bodies. The title principal medical officer should therefore be used in future.

With regard to the remuneration the committee was satisfied that considerable economies had been effected as a

consequence of Dr. Cuff's advice and reports, especially in such matters as dietary of patients and purchase of goods, and this, coupled with the increase in work referred to; justified some addition to the present salary. The committee suggested an increment of £50 per annum and pointed out that even with this the post would not be so remunerative as that of many of the medical superintendents, who had the opportunity of adding to their incomes by students' fees.

The committee recommended:—

That, subject to the sanction of the Local Government Board, the title of Medical Officer for General Purposes be altered to that of Principal Medical Officer, and that the remuneration attached to the post be increased from £850 to £900 per annum.

This was agreed to.

THE FESTIVAL DINNER OF THE LONDON LOCK HOSPITAL.

THE festival dinner of the London Lock Hospital and Rescue Home was held at the Whitehall Rooms of the Hotel Métropole on Nov. 4th, when the Duke of DEVONSHIRE presided. Covers were laid for more than 100 persons, and the company present included Lord Kinnaird (treasurer and chairman of the committee of management), Sir Thomas Barlow, Sir Richard Douglas Powell, Sir Malcolm Morris, Sir Francis Champneys, Sir Arthur Downes, Sir John Collie, and Sir Alfred Pearce Gould.

The loyal toasts having been duly honoured, the CHAIRMAN, in proposing the toast of the evening, "Prosperity to the London Lock Hospital and Rescue Home," said that all present had met with a sense of the need for doing something towards dealing with a great national and social evil. The London Lock Hospital, he believed, was the only one of its kind throughout Great Britain, and it was one which, for obvious reasons, was not talked about publicly as were other institutions which ministered to the suffering. It was called into existence to grapple with a very serious question; the work already done had been justified, and the work which remained to do was enormously important. To-day they had met under circumstances which could not have been contemplated a short time ago. The nature of the evil which had to be confronted had been within the last few months very vividly and painfully brought to the notice of the public, and many present must be viewing with satisfaction the result of their efforts. A great step forward had been taken by the State in the appointment of the Royal Commission to inquire into the prevalence and prevention of venereal diseases, and he believed that it would be possible by concerted action, if not to exterminate them, at any rate to prevent much of their evil effects. Any information that the Lock Hospital possessed which would help the Commission would be placed at the disposal of that body by the staff of the institution. The evil was not merely a national or social one, but an international one of far-reaching importance. With due restriction on his words, he ventured to say that any help extended to the hospital in a financial way must be regarded not only as an act of generosity but as an investment as well; for, after all, could there be any better investment than the security of national health? The probable effect which the lessening of the prevalence of venereal diseases would have upon the rates must be remembered in this connexion, while already the institution for which he was pleading had done much in this direction. If the work of the Lock Hospital were better known he was sure that greater assistance would be given to it. The institution had hitherto been kept going by voluntary contributions—it had been in existence some 167 years—and he asked whether the present generation was less willing than its predecessors to take its fair share of responsibility.

The Chairman coupled with the toast the name of Lord KINNAIRD, who in his reply congratulated the medical profession on the great work that they had done, and said that the institution of which he was the treasurer required at least £9000 to make effective the work of medical science. He was glad that the conspiracy of silence with regard to the particular diseases to cure which the hospital owed its existence had ceased. From its very inception members of the Royal Family had shown their readiness to help the institution which was now in great need owing to the increased demands made upon it. It had been necessary to build a new children's ward, a nursing home, and an out-patient department in Dean-street, as well as a new male hospital, which was just being completed. It was for these reasons that the hospital was in debt, and he confidently looked to the public for the help so urgently needed.

Sir THOMAS BARLOW, in proposing the toast of "The Medical Staff," said the hospital had always been fortunate in securing men in the highest rank of the profession, and it had never been better served than it was at the present time.

Mr. J. ERNEST LANE, in reply, said he believed that the hospital was productive of as much good to the community as any other general hospital in the metropolis or even in the United Kingdom, or perhaps more so.

The toast of "The Visitors" was proposed by Mr. E. PARKER YOUNG and responded to by Sir A. PEARCE GOULD who pointed out the need of a special hospital to deal with a terrible disease.

The toast of "The Chairman," proposed by Mr. J. F. W. DEACON, brought the proceedings to a close.

During the course of the evening the secretary announced a total collection as the result of the dinner of £5430, including the Duke of Devonshire's list of £2487 and Lord Kinnaird's list of £1078.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8805 births and 4754 deaths were registered during the week ended Saturday, Nov. 1st. The annual rate of mortality in these towns, which had been 14·3, 13·6 and 13·1, per 1000 in the three preceding weeks, increased to 13·9 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 13·7, against 13·8 per 1000 in London during the same period. Among the several towns the death-rate ranged last week from 5·9 in Southend-on-Sea, 7·0 in Enfield, 7·6 in Ipswich, 7·9 in Walthamstow and in Carlisle, and 8·1 in Darlington, to 18·3 in Warrington, 18·4 in Walsall, 18·9 in South Shields, 19·1 in Oldham, 21·0 in Cambridge, and 21·1 in West Bromwich.

The 4754 deaths from all causes were 262 in excess of the number in the previous week, and included 509 which were referred to the principal epidemic diseases, against 743 and 536 in the two preceding weeks. Of these 509 deaths, 322 resulted from infantile diarrhœal diseases, 51 from diphtheria, 49 from measles, 45 from whooping-cough, 24 from scarlet fever, and 18 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·5, against 2·2 and 1·6 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 769, 601, and 407 in the three preceding weeks, further declined to 322 last week; of this number 94 were registered in London, 26 in Birmingham, 20 in Liverpool, 14 in Manchester, 11 in Hull, 10 in West Ham, and 9 in Sheffield. The deaths referred to diphtheria, which had been 44, 49, and 38 in the three preceding weeks, rose to 51 last week, and included 10 in London, 3 each in Devonport, Birmingham, Liverpool, and Manchester, and 2 each in Oldham, Leeds, Hull, and Sunderland. The fatal cases of measles, which had averaged 27 in the four preceding weeks, rose to 49 last week; 7 deaths occurred in London, 6 in Stoke-on-Trent, 5 in Bradford, 3 in Leicester, 3 in Stockport, and 3 in Sheffield. The deaths attributed to whooping-cough, which had been 39, 32, and 27 in the three preceding weeks, rose to 45 last week, and included 7 in London, 4 in Liverpool, 3 in Birmingham, and 3 in Oldham. The deaths referred to scariet fever, which had been 23, 16, and 24 in the three preceding weeks, were again 24 last week; 4 deaths were registered in Birmingham, 4 in Manchester, 4 in Sheffield, and 3 in Newcastle-on-Tyne. The fatal cases of enteric fever, which had been 24, 20, and 13 in the three preceding weeks, rose to 18 last week, and included 2 each in London, Derby, Bolton, and Newcastle-on-Tyne.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals,

which had steadily risen from 2112 to 3445 in the eight preceding weeks, had further increased to 3580 on Saturday last; 534 new cases were admitted during the week, against 484, 575, and 530 in the three preceding weeks. These hospitals also contained on Saturday last 1193 cases of diphtheria, 168 of whooping-cough, 79 of enteric fever, and 71 of measles, but not one of small-pox. The 1229 deaths from all causes in London were 45 in excess of the number in the previous week, and were equal to an annual death-rate of 14·2 per 1000. The deaths referred to diseases of the respiratory system, which had been 176, 151, and 178 in the three preceding weeks, further rose to 207 last week, but were 67 below the number registered in the corresponding week of last year.

Of the 4754 deaths from all causes in the 96 towns, 156 were attributed to different forms of violence and 359 were the subject of coroners' inquests. The causes of 25, or 0·5 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and its 14 suburban districts, in Manchester, Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, and in 59 other smaller towns. Of the 25 uncertified causes of death, 6 were recorded in Birmingham, 3 in Liverpool, 2 in Hastings, and 2 in Blackpool.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1062 births and 635 deaths were registered during the week ended Saturday, Nov. 1st. The annual rate of mortality in these towns, which had been 14·7, 13·9, and 14·0 per 1000 in the three preceding weeks, further rose to 14·7 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 14·4, against 13·7 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rate last week ranged from 3·7 in Clydebank, 7·6 in Ayr, and 10·5 in Kilmarnock, to 15·8 in Glasgow and in Paisley, 17·3 in Dundee, and 18 0 in Coatbridge.

The 635 deaths from all causes were 29 in excess of the number in the previous week, and included 82 which were referred to the principal epidemic diseases, against numbers steadily declining from 126 to 62 in the seven preceding weeks. Of these 82 deaths, 34 resulted from infantile diarrhœal diseases, 17 from measles, 14 from scarlet fever, 11 from diphtheria, 3 from whooping-cough, and 3 from enteric fever, but not one from small-pox. These 82 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9, against 1·5 per 1000 in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily decreased from 96 to 19 in the seven preceding weeks, rose to 34 last week, and included 18 in Glasgow, 6 in Aberdeen, 5 in Dundee, and 2 in Kirkcaldy. The deaths referred to measles, which had been 14, 14, and 12 in the three preceding weeks, rose to 17 last week, of which number 12 occurred in Glasgow and 2 in Greenock. The fatal cases of scarlet fever, which had been 6, 13, and 11 in the three preceding weeks, rose to 14 last week, and included 5 in Glasgow and 4 in Motherwell. The deaths attributed to diphtheria, which had been 13, 8, and 11 in the three preceding weeks, were again 11 last week; 6 deaths were recorded in Glasgow and 2 in Aberdeen. The 3 deaths referred to whooping-cough were equal to the average in the earlier weeks of the quarter, and were all registered in Glasgow. The 3 fatal cases of enteric fever occurred in Glasgow, Edinburgh, and Greenock respectively.

The deaths referred to diseases of the respiratory system, which had been 84, 80, and 92 in the three preceding weeks, further rose to 99 in the week under notice; 32 deaths were attributed to different forms of violence, against 26 and 18 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 575 births and 395 deaths were registered during the week ended Saturday, Nov. 1st. The annual rate of mortality in these towns, which had been 17·1, 16·0, and 17·8 per 1000 in the three preceding weeks, fell to 17·2 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these Irish towns averaged 17·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 13·7, while in the 16 Scotch towns it was equal to 14·4 per 1000. The annual death-rate last week was equal to 21·2 in Dublin (against 14·2 in London and 15·8 in Glasgow), 13·4 in Belfast, 15·6 in Cork, 17·8 in Londonderry, 10·8 in Limerick, and 11·4 in Waterford, while in the 21 remaining smaller towns the mean death-rate was equal to 18·8 per 1000.

The 395 deaths from all causes were 14 fewer than the number in the previous week, and included 41 which were referred to the principal epidemic diseases, against numbers steadily declining from 132 to 52 in the seven preceding weeks. Of these 41 deaths, 27 resulted from infantile diarrhœal diseases, 5 from scarlet fever, 3 from measles, 2 from enteric fever, 2 from whooping-cough, and 2 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·8 per 1000; in the 96 large English towns the corresponding rate did not exceed 1·5, while in the 16 Scotch towns it reached 1·9 per 1000. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily declined from 111 to 29 in the seven preceding weeks, further fell to 27 last week; of this number 14 were registered in Dublin, 5 in Belfast, 3 in Cork, and 3 in Kilkenny. The deaths referred to scarlet fever, which had been 2, 4, and 9 in the three preceding weeks, fell to 5 last week, and were all registered in Belfast. Of the 3 fatal cases of measles, 2 occurred in Dublin and 1 in Londonderry. The 2 deaths from enteric fever were recorded in Clonmel, those from whooping-cough in Galway, and those from diphtheria in Dublin.

The deaths referred to diseases of the respiratory system, which had been 54, 48, and 53 in the three preceding weeks, further rose to 61 in the week under notice. Of the 395 deaths from all causes, 118, or 30 per cent., occurred in public institutions, and 4 resulted from various forms of violence. The causes of 13, or 3·3 per cent., of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·5 per cent.

THE SERVICES.

THE King has approved of the appointment of Surgeon-General A. T. Sloggett, C.B., C.M.G., K.H.S., as Director-General of the Army Medical Service, in succession to Surgeon-General Sir Launcelot Gubbins, K.C.B., M.V.O., K.H.S., when the latter vacates his position.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel James Will is placed on retired pay (dated Nov. 5th, 1913).

Brevet-Colonel C. H. Melville has been selected for appointment to hold charge of the Military Hospital at Tidworth, Salisbury Plain District.

Lieutenant-Colonel M. W. Russell, deputy assistant director of medical services to the Eastern Command, has been placed under orders for a tour of service in Malta.

Lieutenant-Colonel C. H. Hale, D.S.O., in charge of the Military Hospital at Maymyo Cantonment, has been granted six months' general leave of absence home from India.

Lieutenant-Colonel D. D. Shanahan, deputy assistant director of medical services to the Ninth (Secunderabad) Division, has been selected for appointment as Senior Medical Officer on board the transport s.s. *Plassy*, which leaves Bombay for Southampton on Nov. 7th.

Lieutenant-Colonel H. D. Rowan has taken up duty in the Dublin District on transfer from the Military Hospital at Tidworth, Salisbury Plain.

Lieutenant-Colonel J. H. Daly has been appointed to hold charge of the Military Hospital at Belfast and Senior Medical Officer of the North Irish Coast Defences in succession to Lieutenant-Colonel J. M. F. Shine, who has been placed under orders for a tour of service in India with the Southern Army.

Lieutenant-Colonel R. W. Wright

has taken over charge of the Military Hospital at Mhow Cantonment.

Major A. J. Williamson has arrived home on general leave of absence from the Military Hospital at Blakan Mati, Straits Settlements. Major S. L. Cummins has taken up duty as Assistant Professor of Pathology and Bacteriology at the Royal Army Medical College. Major S. W. Sweetnam has been reverted to the Home Establishment. Major T. C. MacKenzie, D.S.O., has been selected for appointment as Deputy Assistant Director of Medical Services to the Northumbrian Division, in succession to Lieutenant-Colonel J. Will, who has been advanced to the selected list of lieutenant-colonels on the higher rate of pay. Major E. W. Slayter has been appointed Senior Medical Officer on board the transport s.s. *Dongola*, which left Bombay for Southampton on Oct. 22nd. Major A. F. Weston has arrived home on general leave of absence from Port Royal, Jamaica. Major P. S. O'Reilly, on expiration of service in India, has been appointed to the Eastern Command. Major S A. Archer has taken up duty on the Home Establishment on the expiration of leave of absence from India. Major A. H. O. Young has been selected for appointment as Civil Surgeon at Jullundur Cantonment. Major W. A. Woodside has taken over charge of the Military Hospital at Chakrata Cantonment.

Captain J. L. Wood has been appointed to the Northern Command for a tour of duty. Captain A. S. Arthur has been appointed to the Medical Recruiting Staff at Liverpool. Captain W. K. Beaman has taken up duty at the Military Hospital, Malta. Captain M. B. H. Ritchie, Captain A. M. Benett, and Captain T. W. Browne have been appointed to the medical staff on board the transport s.s. *Dongola*. Captain F. L. Bradish, Captain O. C. P. Cooke, Captain J. Du P. Langrishe, Captain G. F. Rudkin, and Captain W. P. Purdon have been appointed to the Irish Command. Captain F. L. Turner has been granted leave of absence from India, with permission to revert to the Home Establishment. Captain L. A. Andrews has been appointed to the Military Hospital at Cork. Captain W. G. Maydon has taken up duty in the Aldershot Command. Captain H. H. Blake has been selected for appointment as Surgeon to the Headquarters Staff at Peshawar Cantonment. Captain E. T. Potts has taken up duty at the Military Hospital, Cosham. Captain G. B. Edwards has been transferred from the Royal Army Medical Corps College to Leicester for duty. Captain A. C. Amy has been appointed to the staff of the Military Hospital at Agra Cantonment. Captain C. J. Coppinger has been selected for appointment as Clinical Pathologist at the Royal Army Medical College. Captain W. C. Nimmo has taken up duty at the Military Hospital, Aldershot. Captain R. T. Vivian has been transferred from the Military Hospital at the Curragh to Donard for duty. Captain T. S. Blackwell has been selected for appointment as Specialist in State Medicine. Captain G. G. Collett has joined at Quetta. Captain N. E. J. Harding has been appointed to the Cork District for duty. Captain B. Johnson has been granted leave of absence home from India with permission to revert to the Home Establishment at its expiration. Captain C. F. White has been selected for appointment as Specialist in Dermatology and Venereal Diseases, and has taken up duty at the Military Hospital, Dublin. Captain W. L. Webster has been transferred from Limerick to Nenagh for duty. Captain P. J. Marett has been selected for appointment as Specialist in Bacteriology and Prevention of Disease. Captain T. S. Coates has been placed under orders to embark at Southampton on Dec. 19th for service with the Northern Army in India. Captain E. D. Cadell has joined at Aden. Captain F. C. Sampson has taken up duty at the Royal Herbert Hospital, Woolwich. Captain H. J. G. Wells has been appointed to the Military Hospital at Cork on transfer from Poeghane Camp. Captain A. D. O Carroll has been selected for appointment as Specialist in Physical Training and has been appointed to the Aldershot Command. Captain J. A. W. Webster has been placed under orders for a tour of service with the Southern Army in India. Captain D. T. Richardson has been appointed to the Military Hospital at Edinburgh. Captain T. C. C. Leslie has been placed under orders for a tour of service with the Southern Army in India. Captain H. W. L. Allott has been transferred from the Curragh to Newbridge. Captain E. B. Booth has been appointed to hold charge of the Military Hospital at Dundalk.

Lieutenant A. L. Urquhart has been appointed to the London District for a tour of duty. Lieutenant D. T. M. Large has been placed under orders for service with the Southern Army in India.

Indian Medical Service.

Lieutenant-Colonel C. A. Johnston has been appointed to officiate as Agency Surgeon (Second Class) at Mysore. The services of Lieutenant-Colonel J. Crimmin, V.C., have been placed at the disposal of the Commander-in-Chief by the Home Department of the Government of India. Lieutenant-Colonel R. H. Elliot has been granted six months' extension of leave of absence home from India on medical certificate. The services of Lieutenant-Colonel H. B. Melville have been placed at the disposal of the Chief Commissioner of Delhi.

Major L. T. R. Hutchinson, Professor of Physiology at the Grant Medical College, has been granted leave of absence home from India for one year on medical certificate. Major A. Sanderson, Civil Surgeon at Sambalpur, has been transferred. Major F. L. Blenkinsop has been granted three months' leave of absence home from India. Major J. H. Waters has been appointed to officiate as Professor of Materia Medica and Therapeutics at the Calcutta Medical College, in succession to Major J. M. McCay, granted seven months' general leave of absence home from India. Major R. W. Knox, Agency Surgeon to the Foreign Department of the Government of India, has been granted 11 months' general leave of absence home. Major C. R. Bakhle has arrived home on leave of absence from India.

Captain W. J. Fraser, on return to duty from privilege leave of absence, has been appointed Civil Surgeon at Chhindwara. Captain J. M. A. Macmillan, civil surgeon at Amraoti, has been transferred to Hoshangabad as Civil Surgeon. H.E. the Governor of Bombay has appointed Captain T. H. Gloster to officiate as Director of the Bombay Bacteriological Laboratory, vice Major W. G. Liston. Captain M. J. Quirke has been selected for appointment as Deputy Sanitary Commissioner and Inspector of Vaccination in Madras Presidency. Captain A. J. V. Betts has been appointed to officiate as Deputy Sanitary Commissioner of the Western Registration District in Bombay, in succession to Major J. L. Marjoribanks. The services of Captain E. C. Hodgson have been placed temporarily at the disposal of the Government of Madras Presidency. Captain A. J. Lee has been selected for appointment as Specialist in Radiography and Electrical Science to the Sixth (Poona) Division of the Southern Army. Captain W. R. J. Scroggie has been granted leave of absence combined with furlough for two years. The services of Captain F. W. Cragg have been placed at the disposal of the Education Department.

Lieutenant J. C. John has been selected for appointment as Specialist in Ophthalmology.

Territorial Force.

Royal Army Medical Corps.

Colonel Richard Harman Luce, Territorial Force Reserve, Army Medical Service, is appointed to the Honorary Colonelcy of the Royal Army Medical Corps of the Territorial Force in the North Midland Territorial Division, vice Honorary Colonel John C. Bond, who vacates that appointment (dated Nov. 5th, 1913).

Colonel de Burgh Birch, C.B., Retired List, Army Medical Service, is appointed to the Honorary Colonelcy of the Royal Army Medical Corps of the Territorial Force in the West Riding Territorial Division, vice Honorary Colonel John D. Eddison, whose tenure of that appointment has expired (dated Nov. 5th, 1913).

1st South-Western Mounted Brigade Field Ambulance, Royal Army Medical Corps: Captain Alexander Weatherhead French, from the List of Officers attached to Units other than Medical Units, to be Captain (dated Nov. 5th, 1913).

The Royal Army Medical College.

Surgeon-General Sir Havelock Charles distributed the prizes at the Royal Army Medical College on Oct. 29th, and among those present were Surgeon-General A. W. May (Medical Director-General of the Navy), Surgeon-General Sir James Porter, Surgeon-General Sir Francis Trevor and Colonel B. M. Skinner (Commandant of the College). Sir Havelock Charles, after referring to the necessity for keeping up with the progress of medical science, said that there should be no rivalry between the Indian Medical Service and the Royal Army Medical Corps; neither could progress if the other was hurt.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1279.*)

XXVI.—DERBY: ITS INSTITUTE AND ITS WOMEN WORKERS.

THE chief grievance at Derby, as at Chesterfield, is the Approved Institute, which employs whole-time medical officers and does its own dispensing. Its official title is the Amalgamated Friendly Societies Medical Aid Association; but it is usually known as Macklin-street Institute. The women members, I am informed, who are not insured under the Act pay 1*s.* a quarter for medical attendance and medicine, and also pay 2*s.* a year for each child. Of the 4000 or so members about half are insured under the Act; and now in consequence of the new Memorandum issued by Mr. Masterman the full 9*s.* are to be received for each insured person. The institute is in no wise a national undertaking. It is an association of Friendly Societies founded by voluntary effort and private enterprise, but with the 9*s.* in part contributed from the National Exchequer it will be placed in a privileged position. The Insurance Act creates panel medical men and panel dispensing chemists, but the recent circular gives special facilities and financial advantages to institutions that compete disastrously against those on the panel. This is the case at Chesterfield more than at Derby, but to a large extent we find the same at Derby. So flagrant is this contradiction of interests that more than one person has expressed the opinion that it is a deliberate attempt to weaken the panel medical service. It has perhaps occurred to the Government that the panel medical men by joining together may become too powerful. They will be responsible for the health of 14,000,000 people, and if they did refuse to work the machine it would be impossible to replace them. This may well be considered dangerous, and the Government is represented as looking about for another basket in which to place at least a few of its medical eggs. The Approved Institutes might supply this want. They might even be so developed as to become the means of creating an embryo State Medical Service. This latter suggestion, though made by several practitioners, seems to me to be too theoretical and does not fit the actual facts. The fundamental force of a State service is not the pay the State servants receive but the prestige they enjoy. Now if there is one thing which the whole-time medical officers of such institutions do not enjoy that is prestige. If we examine the history of such institutions as they existed in the days of the Battle of the Clubs, and as they still survive, fortunately in but comparatively rare instances, under the Insurance Act, a lengthy and distressing record of disappointment upon disappointment will be found, followed by dismissal after dismissal. The fact of course is that the failures in the profession very generally applied for such posts in those days and the societies they served would sometimes have fallen to pieces but for the fact that there was generally on the staff one or two really well-behaved and thoroughly competent medical officers. We do not want this situation over again; such institutions and their employees do not rank high enough in the public estimation to provide the foundation for a public medical service.

The Institutions Revive the Old Club Grievances.

Though to-day 9*s.* must by law be given annually where formerly 3*s.* 6*d.* or 4*s.* were voluntarily subscribed, it is doubtful if the medical service has in any way improved in the institutions. Is it not probable, on the contrary, that the attendance may be worse rather than better? This may be the case—owing to lack of time, if for no other reason—where the number of persons actually entitled to medical aid has greatly increased, without any corresponding increase in the medical staff. To those who know the immense number of patients who have to be seen in a very short time it may be a matter of surprise to find that so many persons have enrolled themselves as members of such Approved Institutions instead of selecting one of the panel medical men. But this is in part explained by the fact that these institutions are supported by unofficial canvassers, that each member is interested in pushing the concern to which he belongs and in which he has invested some of his savings. Commissions, it has been somewhat widely asserted, are in some instances paid to those who recruit new members. Yet while so anxious to increase their membership many of these institutions are under-staffed, a fact that is proved by the advertisements for additional medical officers. The supply of practitioners willing to accept positions not approved by the profession as a whole is much smaller than it used to be, and the institutions are more successful in recruiting members than in securing an effective and sufficiently numerous medical staff. Then there is undoubtedly a considerable amount of personal pressure exercised, in regard to which the following case occurring at one of these institutions was brought under my notice. Before the Act six members of a family belonged to the amalgamation of Friendly Societies which afterwards became an Approved Institution. Three members had to insure under the Act, and they at once profited by this to leave their old club medical man, who is now the medical officer of the Approved Institution, and select a medical adviser from the panel. When, however, the managers of the institution heard of this they refused to keep the three non-insured members, for they evidently wanted the 9*s.* from each of the three insured members as a condition for giving medical aid at a much lower rate to the three non-insured members. This seems to show that the money received from the insurance fund will in part be devoted to non-insured members. Of course, this should not be; but will and can the authorities insist on reliable proofs being given that the 9*s.* are not in part spent on those members of institutions who do not pay anything like 9*s.* a year each? Also, what will the medical officers of these institutions get? Will it be anything like the 7*s.* received by the panel medical men? It is sufficient to ask the question, and the members of the profession are indignant that these opportunities of sweating medical men should exist.

The Prestige of the Panel Medical Man.

The institutions endeavour to enrol as members insured persons on the ground that they will provide medical aid for their uninsured dependents at very low rates. To this, the reply is made that, as insured people now enjoy the great advantage of being able, for a very small sum, to select their own medical attendant, they should be prepared to pay higher rates for their uninsured dependents. This, however, is an argument that only applies to the better class practice. For instance, there is at Derby a general practitioner who lives on the edge of a very large working and labouring class district. Among these people only one out of four ever paid him his fees. Now he is receiving 7*s.* a year from quite a number of them. Nevertheless, he hardly expects these poor people to pay fees for their dependents when they never used to pay fees even for themselves. Another practitioner, who as a Poor-law medical officer attended a number of patients, now obtains 7*s.* a year from many of these people who are on his list. Thus the Insurance Act has removed the stigma of pauperism in all these cases, and this is no small benefit. Indeed, it is the sense of self-respect that needs cultivating and should be applied to every detail in the working of the Act. The patient must have that sense of dignity that will make him refuse to put up with the worst phases of contract practice, and the practitioner must have too great a respect for his profession to tolerate conditions which may cause him to attempt to do the work in a hasty and degrading manner. That is how these institutions must be fought. The panel medical man must prove his superiority by freedom from the abuses associated with club practice, and now revived in connexion with approved institutes. In such an endeavour the Government should lend its assistance. The Insurance Commissioners are there to see that the best medical service is provided, so they should support in preference those practitioners on the panel. The services provided at institutions are rarely good enough to attract the well-to-do and better educated among the insured public, and this tendency to avoid the institutions should be encouraged. At Derby and Chesterfield several practitioners urged that it was their duty and in keeping with their better interests to make every endeavour thoroughly to

satisfy their panel patients, thus keeping them from the institutions. It is also better to defer discussing the position of uninsured dependents till the popularity of the panel medical men is well established, when it will be much easier to discuss terms. At present many persons remain in the institutions, here and elsewhere, because they enjoy good health, and they think that if they were ill they would send for the nearest practitioner and pay him the usual fees. These indolent persons, who very generally represent from the insurance point of view excellent lives, would be more serviceable if inscribed on the lists of the panel medical man.

Useful Statistics at Derby.

At the last Census the population of Derby was 123,410. Actually the Insurance Committee has duly tabulated and filed all the necessary details concerning 42,000 insured persons, but by the time the last available person is enrolled the number will be about 44,000, representing a good third of the entire population. Here, as at Nottingham, a very large proportion of the workers are women. But, unlike that town, and in fact any other place where I have made the inquiry, the clerk of the Derby Insurance Committee has kept separate records for men and women, and was therefore able to give at once positive figures, the proportion of women insured being 41 per cent. The clerk felt certain that sooner or later the Government would ask for such figures, and it was much easier to start the record from the beginning than to try to work out the comparative figures afterwards. At Nottingham, without any figures to go upon, it was suggested that 40 per cent. of the insured were women. Very strong opinions were expressed at Derby that the proportion was under-estimated, it being obvious that there were more women workers at Nottingham. As it is now positively proved that the proportion is 41 per cent. at Derby, it may be as high as 50 per cent. at Nottingham. This is a most serious matter from both the financial and medical point of view, as women entail a much greater drain on the funds. The women at Derby work at printing and in mills for hosiery, surgical bandages, and lace making. The wages are about 10 to 15 per cent. lower than the Nottingham standard, and there are a great number of women at Derby who only earn 7*s.* 6*d.* a week. The proportion of sickness among women workers is high, especially where they are not living with their families, as the Approved Societies have found out, much to their concern. There are 46 medical practitioners on the panel, including the three medical officers of the Medical Aid Institute. Of the insured persons about 2000 have not yet selected a medical man. No official complaints have been made concerning either the practitioners or the chemists. The latter received 80 per cent. of their claims for the first quarter of the year, but were paid in full for the next two quarters, and at the end of the year they will receive the balance due to them from the first quarter. To do this, however, it will be necessary to take the floating 6*d.* The panel practitioners have received what is due to them regularly throughout the year.

The Women Workers of Derby.

In regard to the women workers at Derby I had the advantage of a conversation with a leading female practitioner. This lady's panel list was not extensive and consisted of a large proportion of young girls. For the most part they went straight to her very soon after they were insured. The Act, she thought, would be of great benefit because it enabled those on the panel to detect and to check anæmia in its early development. Formerly these patients never sought for medical advice or treatment till they were quite ill. My informant had been attached for many years to a large provident dispensary, and had there treated more than 1000 women and children. This enabled her to obtain a good insight into the conditions of life among these women, most of whom were spinsters. She had but little purely gynæcological work to do, but gonorrhœa was very prevalent among the young women and girl workers. This, of course, showed that the insufficient wages are supplemented by some form of prostitution. The wages are about 9*s.* 6*d.* in factories, or 1*s.* a week less than at Nottingham. Most of the unmarried workers lived with their families, but nevertheless gonorrhœa was far too prevalent among them. Many of the girls were, when thus afflicted, afraid to visit her as she gave them "a straight talk," and they went to quacks and herbalists instead, so there were probably more cases of venereal disease than she had seen, and this was indeed a most serious and disastrous state of affairs. But now owing to the Insurance Act much more light will be thrown into these dark corners of the labour world. Among the women themselves the Act is very popular.

In Derby, according to the experience of the same practitioner, there is no really abject poverty, but a low standard of living is widespread. There are many semi-respectable slums, if they may be so described. It would be difficult to find a household with a total weekly income of less than 25*s.*, and the rents for cottages range from 5*s.* upwards a week. Thus there is not abject poverty. But it is a clay soil and the land lies very low, so there are much anæmia and rheumatism. The mothers, I was told, were good in respect to feeding their infants from the breast, and there was no special trade disease, unless it be indigestion produced through bending over tables and work.

Of course, there is a sort of malingering. Women are especially tempted to combine nursing with the desire to finish arrears in housework. The other day a woman took her daughter to see my informant, and asked whether the girl was not in need of a week's holiday. The answer was prompt and sharp: "Yes, but not a week, it must be a fortnight. Also it must not be at home. A week's holiday in a slum will not do your daughter much good. She must go to a convalescent home, away in the country, where she will have good air and good food and plenty of outdoor exercise. The convalescent home will cost 8*s.* 6*d.* a week and from the insurance you will get 6*s.* 6*d* to 7*s.* 6*d.*, so this will cost you about 1*s.* per week." Needless to say this did not meet the mother's view, for she hoped to have her daughter at home for a week to help her in the housework. Instead of getting help, she was called upon to pay a few shillings and was much disappointed, though the holiday suggested would have done good in building up the girl's constitution. Though this would cost a little money at first, it would prove economical in the long run by preventing much subsequent sickness. But it is difficult to induce both individuals and institutions to adopt such a far-sighted policy.

(*To be continued.*)

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

The Motor Exhibition at Olympia, London.

TO-DAY (Friday, Nov. 7th) the Twelfth Motor-car Exhibition at Olympia opens its doors, and should attract considerable attention, not only from medical men in search of cars but also from medico-automobilists in search of methods of adding to the efficiency and convenience of their cars. A preliminary inspection whilst preparations were in progress confirms the general opinion that the show is much like its predecessors, except that the number of exhibitors has increased. Exhibitors of British origin predominate, but Austria, Belgium, France, Germany, Holland, Italy, Spain and America each contribute. The present tendency is not so much in the way of alterations in design as in improvements in construction and material, and in attention to minor details. Certainly a striking feature of the show is the number of cars which may be said to be suitable alike for the means and for the requirements of the average medical man. It has not been possible to view with sufficient detail the many exhibits so as to publish in this number of THE LANCET a detailed account of the show; but exhibits likely to be of use or of interest to medical men will be examined and reported upon in an early issue. The chief points noted at the moment were the general increase of accessibility, a growing use of detachable wheels and rims, and a tendency to an increase in the size of tyres. A large number of makers now fit dynamos for lighting cars, and the fashion of selling the car complete in every way ready for the road has become much more universal. The modern tendency to avoid all actual labour is reflected in the provision of self-starters. As has been more than once mentioned in these notes, there are several excellent devices for this purpose on the market, working either by electricity or compressed air. The avoidance of the exertion required to

pull the starting handle round may not seem to justify the extra expense, except where the increasing class of women drivers is concerned. Anyway, those who do find the exertion of starting their cars irksome will have no trouble in choosing a trustworthy contrivance.

Prices, on the whole, are much lower, and, what is more, many of the cars, by reason of their improved efficiency, now give much better value for the money. In the matter of coachwork distinction in style is more noticeable than before, and pointed radiators, sloping bonnets, and curved dashes combine with elegance in style and tone in coachwork. The exhibition will remain open until Saturday, Nov. 15th, and the price for admission is 1*s.*, excepting on Tuesday and Thursday up to 6 P.M., when it is 2*s.* 6*d.* and 5*s.* respectively.

On the Purchase of a Car.

One of the most usual queries which the writer receives is, "What make of car do you advise for a doctor?" Naturally, it is invidious in these notes specially to recommend any one particular make, though frequently some five or six types can be suggested which will fulfil the needs of the inquirer and from which he should be able to make his choice. The one point which should be borne in mind by a medical man in search of a car for professional use is that the chief cost in the maintenance of a car is the tyre bill, and therefore he who wishes to keep his running expenses down should not get a bigger car than he can afford to keep up. The lighter the car the lower the tyre bill, and also the lower the repair bill. Mere cheapness of initial cost does not always mean low running expenses. A cheap car may prove to be an expensive one. Good design, first-class materials, and care in erection eliminate many repair bills. So it is cheaper to draw a bigger cheque at the beginning than to have to meet many expenses during the running of the car. Another point to bear in mind is the question of accessories. As a result of the American fashion many cars are now sold, to use a common term in the advertisements, "Ready for the road"—i.e., complete with hooter, lamps, hood, with side curtains and wind screen, tyre pump, jack, kit of tools, including tyre levers and Stepney or spare wheel, all of which must be had. Those who like can, of course, add such luxuries as a clock, speedometer, exhaust whistle, dash-lamp, &c. For less than £200 a light two-seater is now procurable, and one, too, that will be fairly silent, reliable, and economical. Of course, if the limit be raised to £250 or £300, a much larger choice presents itself, and a four-seater could be obtained.

The Waverley Light Car.

In the two-seater 10–12 h.p. Waverley Car, the Light Cars Company, Limited, of 115, Great Portland-street, London, W., have produced an automobile that is excellently suited to meet the doctor's demand for a medium-powered car, equipped and ready for the road, at a moderate price—viz., £225. It is always important, in the case of light cars, to distinguish between those that are built for speed only and those that are designed for accommodation. The Waverley has a London built and very roomy body, and has a particularly good spring suspension to the back wheels; also double laminated springs which are bolted direct to the back axle, and thus tie tongue rods and shackles are eliminated. I had one of these cars for a week-end test and gave it a good 150 miles sampling through London traffic and up and down some of the really severe hills round Guildford. I was impressed by the extreme smoothness of the driving effort at moderately high speeds, the freedom from engine vibration, and the flexibility. The frame is of pressed steel, and the engine is a four-cylinder monobloc with 65 mm. bore and 130 mm. stroke. The valves are all on one side, the inlet being operated by overhead rockers, with adjustments on the rods that lift the operating tongues. The crank shaft has two bearings, and the timing gears are operated by means of a spring drive, thus eliminating noise and wear. Lubrication is mechanical, with a sight-drip on the dash. A Zenith carburetter is fitted, and the ignition is by a Bosch fixed-time high-tension magneto. The cooling is by thermo-syphon and a belt-driven fan, with an efficient radiator. The clutch is of the ordinary leather-faced cone type, and three forward speeds and a reverse are operated by a gate selective sliding gear. Both the brakes act on the back axle and are worked by expanding cams inside the brake drums. As a result of my test I found the steering facile and the engine answered rapidly to the depression of the accelerator pedal. The car had a good turn of speed, and behaved throughout the trip in a satisfactory manner. The petrol consumption was over 30 miles to the gallon.

A plaint of the owner driver is inaccessibility, and many a motoring doctor has complained to me of bruised knuckles and wasted time when trying to do some small adjustment or repair. In this car the magneto can be released by undoing a thumb-screw; the undoing of another discloses the valve tappets, and the petrol jet can be taken out in a trice. The oil-tank is replenished from on top and outside the dash, and even the cardan shaft can be greased with a fair amount of comfort. I think if I were buying a car these facts would greatly influence my decision. An important point with doctors is starting the engine from the cold. I found this car to start easily after a night's rest with a sharp swing, and no special effort was needed to give that swing. I also noticed that the fittings of the car were neither cheap nor shoddy, and that these parts, which so often on low-priced cars "tell the tale," were as well made and finished as could be desired.

Starting Difficulties.

A good many letters have been received from time to time in which complaint was made of trouble in getting the motor to start from the cold. It may be healthy for the owner-driver to have to crank the starting lever for some time in the morning, but it is not a good commencement for a heavy round of visits, nor can the time be usually devoted to this exercise. All that is needed for easy starting is a cylinder full of gas, a spark to explode the gas, and a proper compression of the gas. Many carburetters have two jets—one for starting and slow running, the other and larger one coming into play when the throttle is opened. Cars thus fitted start more easily with the throttle only slightly open, as then the smaller jet is used and the suction on that will get a suitable mixture more easily. Leaks in the induction pipe joints, by admitting air, reduce the suction on the jet, and thus cause a difficulty. An easy test to see if the carburetter is giving off a mixture is to take out a sparking plug and to apply a match to the sparking-plug hole; a slight puff will then show whether the fault is with the carburetter or not. Shorting the plugs on the cylinder will reveal if the ignition is at fault. The introduction of a few drops of a mixture of petrol and ether into the cylinder through the compression tap or a sparking-plug hole will provide the needed cylinder of gas if the compression is too poor to suck it in, or the weather too cold to permit the petrol to vaporise.

Leaky Back Axles.

Occasionally oil leaks through the end of the back axle, and this is neither good for the tyres nor the appearance of the car. Fibre washers fitted inside the end of the tubular back axle casing will usually effect a cure. Some advocate using a heavier lubricant for the differential, but this I would not advise, as in many instances the heavy lubricant will not get into the inside differential casing, and as a result one of the spider pinions might become seized, with, of course, disastrous results. It is better to have to remove a back wheel, say, once every two or three months to fit a new washer, than to run this risk.

BRISTOL AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol: Congregation for Conferring of Degrees.

THE usual ceremony for the conferring of degrees was held in the Victoria Rooms on Oct. 22nd. It was noteworthy in several respects; there were only three medical graduates, there were no honorary degrees, and the usual tumult was conspicuous by its absence, the students preferring to vent their high spirits in other ways. They made up for their unnatural quiet a day or two later, however, by an organised attack on the premises of the Women's Social and Political Union, which are—or rather were—close to the University buildings. On the morning of the 23rd the pavilion at the University sports ground was found to be in flames,

apparently as the result of a suffragette visit; and the students, many of whom lost garments and other property in the conflagration, took their revenge by smashing the windows of the W.S.P.U. shop and stripping it of furniture, which they burnt in a bonfire in Queen's-road, a main western thoroughfare. No arrests were made.

Bristol Open-air School.

Last week the Lord Mayor of Bristol formally opened the new open-air school at Knowle, a suburb on the Somerset side. It will accommodate 65 children; at present it is financed by a voluntary committee who are appealing for support, but it is expected that in two years or so the Education Committee, who are already coöperating in various ways, will take it over completely. It is designed for weakly and anæmic children, and for those suffering from glandular tuberculosis and similar ailments. In addition to a large shed, open on the south side, in which the lessons will be given, there is provision for feeding the children and drying wet clothes. Tram fares will be provided also. It is hoped that parents will contribute to meet the expenditure wherever they can. Meantime the project for the establishment of a sanatorium for tuberculous children has been interrupted; the inhabitants of Kingswood, a district which, though virtually within Bristol, belongs for administrative purposes to Gloucestershire, have successfully petitioned their county council to stop the establishment of a sanatorium in their neighbourhood, where it had been proposed to adapt existing premises to that end.

Chadwick Public Lectures.

Dr. Leonard Hill has delivered two out of three lectures to be given under the Chadwick Trust on Heating and Ventilation, in the large hall of the University of Bristol. Admission is free to the public, and the opportunity of learning something of these important subjects from a first-class authority has been eagerly taken by considerable audiences.

Bristol Medical School Dinner.

The annual dinner of the Bristol Medical School will take place at the Royal Hotel on Nov. 18th at 7.30 P.M. The president will be Dr. P. Watson-Williams and the guest of the evening is Sir Felix Semon, K.C.V.O.

Long Fox Lecture.

The eighth Long Fox lecture will be delivered on Nov. 18th in the physiological lecture theatre of Bristol University by Professor F. H. Edgeworth, the subject being the Cranial Nerves, their Motor Nuclei and Muscle Sensory Fibres. Sir Isambard Owen, the Vice-Chancellor, will occupy the chair.

Plymouth Public Dispensary.

Dr. J. E. Cheyne Wilson has been honorary physician to the Plymouth Public Dispensary for about 17 years, and recently the committee of that institution decided to make the appointment a salaried one, and advertised the post locally. Dr. Wilson was a candidate, and it was generally presumed that he would have the position, but the committee did not elect him. They, however, appointed him honorary consulting physician, but in a letter to the secretary Dr. Wilson declined the post, stating that he could not with dignity do otherwise. A considerable amount of sympathy is felt for Dr. Wilson in Plymouth, and the *Western Morning News*, in commenting on the matter, says: "Such treatment of a medical man of blameless repute, who has rendered long and meritorious service, is not without precedent amongst Plymouth institutions, and it displays a spirit which is by no means calculated to strengthen public confidence in their management."

Medical Officer of Health of Plymouth.

Mr. Frederick Mann Williams has resigned the post of medical officer of health of Plymouth after 21 years' service, but he will still retain the appointment of medical officer of the Plymouth Port Sanitary Authority. The Plymouth sanitary committee in accepting the resignation resolved "to acknowledge the valuable and faithful services rendered to the borough by Mr. Williams."

District Medical Officership of Ilfracombe.

The difficulty which the Barnstaple board of guardians have had in filling the vacancy for the appointment of district medical officer of Ilfracombe seems as last to have been settled. The guardians recently decided to increase the salary to £100 per annum, and four candidates applied for the post, with the result that Mr. W. F. Stevenson was eventually elected. As has already been remarked in THE LANCET, if an adequate remuneration had been offered in the first instance, there would have been no trouble in obtaining applicants.

Vaccination in the West of England.

There has been a very serious decrease in the number of vaccinations performed by the public vaccinators in the West of England, and this seems to have attracted the attention of several boards of guardians, for the resolution proposed by the Blackburn board, to which allusion was recently made in THE LANCET, has been supported by many of the West of England boards, the most recent to do so being those of Honiton, Okehampton, and Crediton.

Poliomyelitis in Devonshire.

At a meeting of the Bideford town council held on Oct. 30th it was reported that there were four cases of poliomyelitis in the borough.

Nov. 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Illness of Sir Donald MacAlister.

I LEARN with regret that Sir Donald MacAlister, Principal of Glasgow University, has been somewhat seriously ill during the past week. During the last day or two his condition has improved, but it will be some weeks before he is able to attend to business.

Aberdeen School Board Health Report.

In his fourth annual report of the medical inspection department of the Aberdeen School Board Dr. George Rose, medical officer, reports that a great many of the children suffer from burns or scalds, many of them caused by the application of poultices to relieve trouble in the chest or abdomen. The number of cases of appendicitis had gone up. A growing objection to vaccination is noted, the total average of the unprotected children of all ages attending school being 3·7 per cent., and the average of unprotected children under 6 years of age rising to 8 per cent. Dr. Rose reports that footgear shows an improvement in both quality and shape; a great many of the children entering school for the first time had shoes built on natural lines. Among the older girls also pointed toes had disappeared to a large extent. As regards clothing, he finds the majority of parents ignorant of what constitutes sufficient clothing for a healthy child, and gives a list of the necessary clothing. Blepharitis is common among the children. A card giving the nature of the disease and the method of cure is given to parents whose children are suffering from this trouble. The report goes on to say that "medical inspection has shown that one-third of the children suffer to a greater or less degree from the ignorance of their parents regarding the elementary principles of feeding, clothing, and home hygiene, and that a large percentage of illness and positive disease are due to such ignorance. Indeed, it might well be said of the children as of the people of old, 'They perish for lack of knowledge.' And this could and should be remedied. A knowledge of the elements of personal and household hygiene could be as easily communicated to the children as the elements of English grammar. If the curriculum be overloaded already something of less importance must be jettisoned, for if children are to be taught anything of the laws that concern their health and well-being it must be done in school. Parents cannot teach their children what they do not themselves know."

Presentation to Sir George Beatson.

On the afternoon of Oct. 29th the superintendent and past assistants and house surgeons of Sir George T. Beatson met in the board-room of the Glasgow Western Infirmary, and presented their former master with a rose-bowl and ornaments as a recognition of their high appreciation of his services, on the occasion of his retirement from the active staff and his appointment to the honorary consultant staff of the institution.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Insurance Commissioners and the Medical Profession.

AT a meeting of the Irish Medical Committee held in Dublin on Oct. 30th the metropolitan surgeon who had been negotiating with the Commissioners attended and explained that since the notice convening the meeting to be held that day had been issued the position of affairs had entirely changed, the National Health Commissioners having expressed their willingness to meet the deputation from the Irish Medical Committee, and he laid before the committee the basis for negotiations, which was afterwards considered by the Irish Medical Committee and arranged as follows for their interview with the Commissioners:—

1. That the £91,000 will be paid to the medical profession minus working expenses, and according to a scheme to be decided on in consultation with this committee.
2. That there may be a deduction of 1*d*. per 2*s*. 6*d*. for management expenses.
3. That the moneys will be disbursed direct to the profession by the Commissioners.
4. That all present appointments are to end on Jan. 14th, the date up to which contracts have been signed.
5. That all appointments after our meeting with the Commissioners are to be made after a consultation between the Local Medical Committees, Insurance Societies, the Insurance Commissioners, and this committee. That such appointments be made from men selected by the Local Medical Committees after the precedent of Belfast.
6. That no preference is to be given to men already acting as advisers under the Insurance Commissioners.
7. That should it be found after consultation between our committee, the Irish Insurance Commissioners, and the representatives of the societies that referees must he appointed, societies demanding such officers should be asked to pay half the salary, thus freeing more money for distribution amongst the profession.

A long letter had been received from the Insurance Commissioners (*a*) asking the Irish Medical Committee to show its authority as the representative of the entire medical profession in Ireland; and (*b*), announcing further that a Departmental Committee had been appointed for the purpose, *inter alia*, of taking such evidence as may appear to them would prove helpful in the consideration of any scheme for the medical certification of insured persons, announcing that, amongst other bodies, the Local Medical Committees had been requested to give evidence before this Departmental Inquiry. To this letter the Irish Medical Committee decided to reply: (*a*) That it is the only body representative of the medical profession and medical societies in Ireland, and that it has plenary powers to deal with the question of the distribution of the grant-in-aid on a basis of 2*s*. 6*d*. per caput. (*b*) In reference to the Departmental Committee of Inquiry, it was decided to reply that the Irish Medical Committee would coöperate in placing at the disposal of the Commissioners such evidence as may assist in formulating the scheme when the Committee would be made aware of the nature of the evidence required.

Demand for a Vice-regal Commission on Housing.

Last week the Irish Government, represented by the Lord Lieutenant and the Chief Secretary, received at Dublin three influential deputations whose object was to press for the appointment of a Vice-regal Commission to inquire into the question of the housing of the working-classes in Ireland. The bodies represented were the Women's National Health Association, the Housing and Town Planning Association, and the Dublin Citizens' Association. Some of the speakers made the demand on behalf of Dublin alone, while others wished to give the Commission a wider scope. The most important facts bearing on the question were those furnished by Sir William Thompson, Registrar-General. He compared the condition of Dublin with that of certain other large cities. In Dublin in 1911 there were 21,133 one-room tenements containing a population of 69,000; in Bristol, a city of nearly equal population, there were only 3700 one-room tenements, containing 5000 persons. The respective percentages of those living in one-room tenements to the total population were, for Dublin 26 per cent., and for Bristol 1·5 per cent. In Liverpool the figure is 2·3 per cent.; in Edinburgh, a city which has many historical and social similarities to Dublin, 5·6 per cent. In Glasgow it is 13·2 per cent., and in Belfast 0·3 per cent. The smaller Irish towns are in much better case than Dublin. Limerick has 7·9 per cent. of its population in one-room tenements, Cork 4·7 per cent., Londonderry 3·1 per cent., and Waterford 2·9 per cent. The death-rate, the infant death-rate, and the tuberculosis death-rate are all much higher in Dublin than in the other cities mentioned. Mr. Chart gave a valuable analysis of the social and economic condition of the inhabitants of three typical tenement houses, let out to 26 families numbering 96 individuals. Most of the occupants were labourers, carters, porters, and charwomen. Few earned over £1 a week, and many said that their earnings only averaged from 10*s*. to 15*s*. a week. He concluded that 2*s*. to 3*s*. a week was as much as such a tenant could pay for housing. The replies of the Lord Lieutenant to the arguments of the deputation were sympathetic but formal, while Mr. Birrell, though he also was sympathetic as regards the magnitude of the evil, mainly devoted himself to giving reasons for preferring an inquiry by a committee of the Local Government Board to one by a Vice-regal Commission. His arguments were that the latter method of investigation would cost more money and would entail unnecessary delay. It may be said definitely that public opinion will not be satisfied by Mr. Birrell's proposals. The Local Government Board is one of the bodies which, at any rate, by sin of omission, are responsible for the present state of affairs, and the public will not be satisfied with an inquiry in merely official hands. Since the date of Mr. Birrell's reply a committee of the Local Government Board has actually been appointed to investigate housing conditions in Dublin. It is not certain that this precludes the subsequent appointment of a Vice-regal Commission. It may, however, succeed in "queering the pitch."

The Milk-supply of Ireland.

The Vice-regal Commission on the Irish Milk-supply presented a unanimous report last week. It deals with (1) the alleged scarcity of milk and (2) its purity. It is found that in the cities and large towns there is no real scarcity of milk, but there is much ignorance as to its value as a food. In the smaller towns there is a partial scarcity in milk. It is suggested that urban authorities should be empowered to contribute from the rates toward the expenses of establishing and maintaining milk depôts. As prevails, I understand, in many rural districts in England, it is in the country that there is an actual scarcity of milk. The Commission suggests that in country areas consumers should organise themselves into milk clubs, and purchase a sufficient daily supply of milk from the creameries. The use of separated milk is also recommended.

Chief Tuberculosis Officer for Belfast.

The Belfast city corporation met in committee on Oct. 28th to appoint a "chief tuberculosis officer" under their new municipal scheme, which is to involve an expenditure of £42,000 a year. The appointment is worth £600 a year. Candidates were invited to apply for the post, and there were actually 16 applicants who sent in their names and testimonials, but as a fact there were really only two candidates—Dr. Andrew Trimble (a former member of the corporation, who resigned the position to become a candidate) and Dr. F. Coates. The former was appointed by 34 votes to 16. Both were excellent candidates, but it was well known six months ago that Dr. Trimble would probably be appointed, so that considerable sympathy is due to the candidates who, in response to invitations, underwent the labour of making their applications.

Ulster Medical Society.

On the evening of Oct. 30th, in the Medical Institute, Belfast, the retiring President, having in a short valedictory speech again thanked the Fellows and Members for the honour they had done him, introduced his successor, Dr. A. B. Mitchell, who proceeded to give his inaugural presidential address on Incapacity following Injury. From his ample experience as surgical referee for the city corporation of Belfast on questions of workmen's compensation after injury, Dr. Mitchell was able to give a most practical lecture as to the duties of the surgeon in such cases.

He advised the greatest generosity to be extended to the injured worker, while at the same time the malingerer should be detected and exposed. His idea was that the injured man's doctor and the doctor of the insurance company (and this really represented the employer) should meet in consultation exactly as in any other occurrence of disease or accident, and decide on the case after discussion. Dr. Mitchell pointed out that in fractures two X ray photographs should be taken in different planes, and showed that unless this was done mistakes might arise, and he suggested that the insurance companies would be wise in their own interests to have an X ray installation fitted up and have radiographs taken. Finally, Dr. Mitchell exhibited a series of most interesting photographs which showed how much work could be done by people who had sustained great injuries to their hands. A hearty vote of thanks was passed to Dr. Mitchell for his address, which was rendered very much more interesting by an excellent series of lantern slides.

A resolution was subsequently carried to make Dr. J. Walton Browne, D.L., an honorary Fellow of the society.

A Correction.

In this correspondence last week there is an error on p. 1281, second column, four lines from bottom. The year 1900 should be *1909*. The year was given correctly in THE LANCET of Oct. 4th, 1913, p. 1025, in a note on the health of Belfast during 1912.

Nov. 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Hygiene of the Barber's Shop.

AT the last meeting of the Société de Prophylaxie Sanitaire et Morale, on the request of the Syndicat des Coiffeurs, Dr. Fouquet read a paper on the transmission of infection by hairdressers and their implements and the hygienic precautions to be recommended by the society in reference thereto. Dr. Fouquet recommended that cutting instruments should be washed in a 1 per cent. solution of carbonate of soda and wiped with a dry cloth. Brushes, combs, and shaving brushes should be freed from accumulated grease each evening by washing in ammoniated soap-water. Metallic instruments should be passed rapidly through a flame before being used again. Brushes and combs should be kept in a hermetically sealed retainer containing a saucer of 40 per cent. solution of formol. Rice powder should be applied only by means of a pad of sterilised cotton-wool, which should be destroyed at once. For the piece of alum commonly applied to cuts and abrasions in different persons powdered alum should be substituted, applied as above with cotton-wool, which should be destroyed after use. Barbers must be forbidden to sharpen their razors by stropping them on the palms of their hands. Regular customers should, if possible, have their own individual apparatus kept for their use alone. The society will be called on to consider these proposed measures and to submit them to the Conseil d'Hygiène with a view to their publication as a compulsory regulation for all barbers, to be posted in their shops. Of course, opposition to these measures is foreseen. Some time ago an attempt was made to impose the employment of a dry heat stove, heated by gas, in which scissors, razors, &c., were to be placed between their use on different persons. In practice for the most part the stove served only as a bid for confidence on the part of the customer, for the same razor and the same scissors always remained in it, while those used were spread out on a table, ostensibly having been sterilised and allowed to cool. Dr. Fouquet accompanied his report with microbiological evidence showing the need for the proposed measures. It had long been known, he pointed out, that syphilis, furunculosis, tinea, and perhaps alopecia, and other contagious diseases of the skin and scalp were transmitted at the barber's. M. Langlais had obtained from a shaving brush taken from a respectable barber's a culture containing 160,000 bacteria per c.c.; and the same observer showed that a razor before being rinsed furnished 7000 bacteria and 26,000 after having been stropped on the hand. As to the piece of alum Dr. Remlinger had obtained 66,000 bacteria per c.c. from sterilised water in which it was dissolved.

The Use of Oxygen in the Insane.

Dr. Toulouse, of the lunatic asylum of Villejuif, has made, in conjunction with his assistant Dr. Puillet, some very interesting observations in reference to the use of subcutaneous injections of oxygen in persons suffering from nervous exhaustion, and even from mental diseases. In various cases of mental confusion with agitation, excitement, and insomnia, Dr. Toulouse has obtained remarkable results. The more acute the condition the more clearly marked are the effects. In simple cases of nervous exhaustion and in epileptics he had also had good results, though less marked and more transitory. The patients themselves, on regaining reason, described the sensation of well-being and immediate relief that followed the oxygen injections. The ultimate bearing of this method cannot yet be definitely settled, but it is worthy of study, at least in those cases in which an intoxication or an infection, which the organism cannot throw off, appears able to improve under very energetic oxidation. Dr. Toulouse does not despair of the successful use of this treatment even in cases of simple mental alienation.

Infant Mortality.

The report of Professor Achard to the Académie de Médecine on the working of the inspection of children of tender years has disclosed the fact that in 1911 the deaths of young children were 20,000 in excess of the usual average. This deplorable fact is attributed to the exceptional heat of the summer, and especially to an epizootic of aphthous fever which at that time attacked the cows in some parts of France, gravely altering the quality of their milk. The same causes have, moreover, led to similar results in neighbouring countries. These causes are temporary, and the later statistics already suggest a return towards the normal mortality. Professor Achard's report also confirms the statement of M. Pinard at the Académie de Médecine that in the provinces the use of the feeding-bottle was largely replacing breast nourishment. The *loi Roussel* forbids a wet nurse engaging herself out before her own child is 7 months old. This law, in force now for 15 years, is causing the almost total disappearance of hired wet nurses. The Academy, therefore, is considering at present a proposition to reduce to four months the time during which the nurse must reserve her milk for her own child.

Death of Professor Le Double.

Professor Le Double, of Tours, died recently from accidental asphyxia with carbon monoxide, the result of a defective heating apparatus. He was born in 1848 and studied medicine in Paris. He settled at Tours, where he became surgeon to the General Hospital in 1878 and professor of anatomy at the Medical School in 1888. In 1898 he was elected a corresponding member of the Académie de Médecine. He was one of the first anatomists of his time. His innumerable dissections revealed a large number and variety of anomalies in the disposition of the osseous and muscular systems and of the veins. He also published some notable volumes on morphological and historical questions relating to medicine. His work (in conjunction with Dr. F. Houssay) on the hairy type in the human race (*Les Vélus*) was very appreciatively reviewed in THE LANCET of August 10th, 1912. He also wrote on prehistoric medicine and surgery, on Rabelais as an anatomist and physiologist, and on Bossuet as an anatomist.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

A Magnificent Gift to the Johns Hopkins Medical School.

THE Johns Hopkins Medical School has received $1,500,000 from the General Education Board, which draws its supplies from Mr. John D. Rockefeller. This is the biggest gift which the Board has made as yet to any one institution. The new foundation will be called the William H. Welch Endowment for Clinical Education and Research, in recognition of the great services rendered by Dr. Welch for medical education in America. The interest of the money is to be used for the salaries of the professors of medicine, surgery, and pædiatrics, their associates and assistants, and to provide the laboratories and clinical paraphernalia to enable them to carry on their

work. The salaries paid will be fixed so as to give the holders an adequate sum for comfortable living, and they will be required to resign all private practice and to devote their lives to the work of research, investigation, and teaching. It is understood that the services of the three selected professors will be available for the public in certain circumstances, but gratuitously. Dr. W. S. Halsted, the present professor of surgery, has agreed to retain his chair under the new conditions.

A Urological Clinic for Johns Hopkins Hospital.

Mr. J. B. Brady recently offered to Johns Hopkins Hospital, Baltimore, the sum of £50,000 for the establishment of a special urological clinic. The first steps towards utilising this gift have now been taken, and contracts have been awarded for the erection of the building, which will occupy three storeys with a roof garden. Dr. Hugh H. Young is to have the direction of the clinic, which it is expected will be open to receive patients within a year.

The Study of Criminology.

Steps are being taken for the organisation of a National Society for the Study of Criminology, which is to be composed of psychologists, sociologists, and medical experts. The study of criminology is becoming more widely extended, and evidences of an awakening in regard to it are forthcoming from many quarters. Among others mention may be made of the recommendations of the Committee on Criminal Punishment of the Chicago Medical Society, suggesting the separation at all times of misdemeanants from felons; the hastening of grand jury and final trials; the extension of the reformatory idea to all criminals except incorrigibles and those charged with capital offences; the appointment of an Illinois State Sentencing Committee to classify all criminals; and the arousing of the interest of the women of the State in their sisters who have undergone penal sentence, with a view to preventing their drifting in crime or vice.

A Woman Research Fellow at Yale University.

The American-Scandinavian Foundation, which was established in 1911 with an endowment of £120,000 by Mr. Niels Poulson, of New York, to foster intellectual relations between the Scandinavian countries and the United States, has established six Fellowships, to which nominations are made by the Swedish and Norwegian Governments, to enable Scandinavian scientists to prosecute research work in the American Universities. The Swedish Government has recently appointed the first woman Fellow, in the person of Miss Ellen Gleditsch, a pupil and associate of Madame Curie in Paris, to study radio-activity in the laboratories of Yale University.

Colonel Gorgas goes to South Africa.

Colonel Gorgas, of the United States Army, whose work as a sanitarian in subduing yellow fever in Cuba and later in rendering possible by sanitary measures the completion of the Panama Canal, where he is chief sanitary officer of the Canal Zone, has received leave of absence to proceed to South Africa to investigate the conditions obtaining in the mines there, where the mortality is notoriously heavy. Colonel Gorgas is a charming colleague, and will doubtless be heartily welcomed by the medical authorities in charge.

The late Dr. James Egan, of Springfield, Ill.

Dr. James Egan, who died from nephritis a little while ago in Springfield, Ill., aged 53, had served as secretary of the Illinois State Board of Health since 1897. Since 1901 he had also been a member of the Board and since 1909 its treasurer. He was an aggressive opponent of illegal practitioners of medicine, incompetent midwives, and "diploma mills." He was a native of Massachusetts but came to Illinois in 1887, and graduated in medicine at the Northwestern University Medical School (then the Chicago Medical College) in 1893. For four years he held appointments under the Chicago Health Department, becoming later secretary of the State Board of Health of Illinois. He was a first lieutenant of the U.S. Army Medical Reserve Corps. Notwithstanding a certain aggressive combativeness of disposition he made many firm and devoted friends to whom his loyal nature endeared him. THE LANCET has on more than one occasion commented editorially on the sensible and practical *Bulletins* which he issued from the Illinois State Board of Health.

Death of Professor Reginald Heber Fitz.

In the death of Dr. Reginald Heber Fitz, which took place recently from gastric ulcer, the medical profession in America loses one of its distinguished pathologists. Dr. Fitz, who was born in Massachusetts in 1842, graduated at Harvard University, and studied subsequently in Vienna, Berlin, Paris, and London. On his return to America he was appointed to the staff of the Massachusetts General Hospital in Boston and became instructor, and subsequently professor, of pathological anatomy in the Medical School of Harvard. In 1877 he became physician to the hospital, and in 1892 professor of medicine at Harvard. He did pioneer work on appendicitis and on pancreatic diseases.

Oct. 25th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

First Dominion Medical Council Examinations.

Dr. R. W. Powell, registrar, Dominion Medical Council, Ottawa, announces the results of the examinations held in Montreal on Oct. 7th. Seventy-one candidates presented themselves and 44 were successful. Eight were referred to the Council, having failed to qualify in not more than two subjects, and 19 were rejected. Most of the successful candidates were from the provinces of Ontario and Quebec. New Brunswick furnished 1, Alberta 1, British Columbia 1, and 2 were from the United States.

Winnipeg General Hospital.

A by-law will be submitted to the ratepayers of Winnipeg, Manitoba, in December for $275,000 for the purposes of the General Hospital. Recently a new wing was opened and other extensive additions made which bring the capacity of the hospital up to 478 beds. The cost of these additions approximated $605,000 on the main building, $54,000 on a nurses' home, and $14,000 on a new residence for the superintendent. Of the total amount only $450,000 have been received by the board of trustees, and as there is a mortgage of $60,000 not less than $275,000 will meet the present requirements. The provincial government will also likely be approached for a grant, as a good many patients come from different points throughout the province.

An Epidemic of Jaundice.

During the months of March and April, 1911, Dr. Malcolm Mackay, of Sherbrooke, Quebec, had 17 cases of acute jaundice under his care. Five were males and 12 females, and 13 of the total number were between the ages of 15 and 25 years. No two cases occurred in the same house. Hearing of other cases at the same time, Dr. Mackay sent a series of questions to all the other medical men in Sherbrooke and received nine replies containing details of some 82 more cases. Sherbrooke has a population of 17,000; and allowing 5 cases of every sort per annum to every 2000 according to Leslie's statistics, Sherbrooke should have had about 43 cases in the course of the year. But there were 99 cases reported in two months. In all the cases there were 34 males and 65 females. Of children under 15 years of age, there were 45 cases; 13 cases in adults over 25 years; the remaining 41 being between 15 and 25 years. More than one case in a house was reported six times by one physician, three times by another, and once by another, while a fourth had five cases in a small orphanage. The greater majority of the cases were found in one ward of the city. Dr. Mackay draws the following conclusions: The disease is infectious; gastro-enteritis is present; the jaundice is of the obstructive type characteristic of catarrhal jaundice; the disease is possibly contagious.

The Canadian Hospital Association.

The annual meeting of the Canadian Hospital Association was held in the new Toronto General Hospital from Oct. 20th to 22nd, under the presidency of Dr. H. A. Boyce, the superintendent of the Kingston General Hospital. The opening proceedings at the first session were enlivened by a discussion upon the sale of noxious drugs. One Toronto coroner averred that the sale of these drugs had increased rapidly in the city during the past few years, and called for an amendment of the Canadian criminal code to deal with this question. The President regretted in his address that hospitals were so parsimonious that they would not send their superintendents to these annual meetings. He also

advocated the standardisation of hospitals and the appointment of a hospital architect by the Government, as many hospital buildings to-day were no better than fire-traps. He thought that through faulty construction nurses were walking miles and miles more than they should. Dr. Thomas Howell, president of the American Hospital Association, submitted a paper dealing with points for inexperienced superintendents in purchasing, receiving, and distributing supplies. The paper advised the coöperation of hospitals in the buying of supplies. By this method much could be gained and nothing lost. The association seemed to approve generally the suggestion that hospitals should share in the public taxes and be put on a plane with parks and libraries in this respect. It was argued that if hospitals could be assured of half a mill rate—i.e., the thousandth part of a dollar—it would help to get rid of the ever-present deficits. The superintendent from the Protestant General Hospital, Ottawa, said that eight years ago a plebiscite was taken in Ottawa on the question of raising a tax for the benefit of the hospitals of that city and the proposal was carried by a majority of 3 to 1; and they were getting double the subscriptions to-day they were getting eight years ago. The rate was first a quarter mill, then a half, and now it is three-quarters. Dr. J. N. E. Brown, formerly superintendent of the Toronto General Hospital and now superintendent of the Detroit General Hospital, with lantern slides explained the features of a number of the greatest hospitals in the world. Dr. Brown seemed to show a partiality for the one-storey pavilions with 50 or 60 acres contiguous to the woods and fields rather than in the neighbourhood of skyscrapers. The Rev. A. S. Kavanagh, superintendent of the Methodist Episcopal Hospital, New York, said they should hail the divorcing of the training school from the hospital with great satisfaction, especially if organised on the same basis as the medical college. He criticised the trade union spirit by which the nurse's price is standardised. Dr. John A. Hornsby, Chicago, called that day blessed when medical staff officers would give their whole time to the hospital and its patients on a stated salary. Dr. E. H. Young, assistant superintendent of the General Hospital, Kingston, was elected president, and Dr. W. J. Dobbie, superintendent of the Weston Sanatorium, was re-elected general secretary.

Abdominal Cæsarean Sections.

A report of a series of abdominal Cæsarean sections by Dr. Fred. Fenton, senior obstetrician and gynæcologist to St. Michael's Hospital, Toronto, and who died in Toronto suddenly during the past summer at the early age of 43 years, appears in the October issue of the *Journal of the Canadian Medical Association*. The cases constituted a consecutive series from July, 1909, to the time of the report at the annual meeting of the Association in June last. Of the 26 cases and operations reported, 16 were done because of obstruction to delivery owing to contractions in the bony pelvis; 6 for ante-partum hæmorrhage with undilated os; 1 each for eclampsia at term, large baby, and stenosis of soft tissues. The history of one case was lost. Five cases were second operations on the same patient, and two patients have subsequently been delivered unaided. All of the children were delivered alive, and all but three left the hospital in good condition. The three who died during the first two or three days were premature. One mother died, but it is claimed her death was not due to the operation. All the operations were done before the membranes were ruptured, before any attempts at delivery per vaginam, only two or three examinations having been made.

Oct. 23rd.

TRINITY COLLEGE, DUBLIN, MONTHLY DINING CLUB.—This club exists primarily to afford more frequent opportunities than hitherto for graduates and members of T.C.D. to meet and, as already has frequently occurred, renew friendships which, formed in undergraduate days, have been interrupted for lengthened periods. The club meets in London each month from October to June, with the exception of May, in which month "The T.C.D. Dining Club" hold their annual dinner. The honorary secretary, Mr. C. T. Nicholson, 27, St. George's-court, Gloucester-road, S.W., will be glad if all members of Trinity College, Dublin, will send him their names and addresses with a view to their receiving further particulars.

Obituary.

EDWARD NETTLESHIP, F.R.C.S. ENG., F.R.S.,

CONSULTING SURGEON, ROYAL LONDON OPHTHALMIC HOSPITAL; CONSULTING OPHTHALMIC SURGEON, ST. THOMAS'S HOSPITAL, ETC.

WE announce with regret the death of Edward Nettleship, which occurred at his house at Hindhead on Oct. 30th. His death removes from the medical profession one who for many years has occupied a foremost position in ophthalmology, and one whose loss will be keenly felt by a large number of colleagues, pupils, and friends.

Edward Nettleship was born in Kettering in 1845, the fourth son of Henry John Nettleship, solicitor, of that town. He was one of six brothers, of whom four attained much distinction in their several professions, and possessed personal characteristics which marked them as exceptional men. Edward Nettleship received his early education at Kettering. He subsequently studied at the Royal Agricultural College at Cirencester and became a member of the college in 1863. He then entered the medical school of King's College, and a year or so later began to study at the Royal Veterinary College. In 1867 he obtained the diploma M.R.C.V.S. and in 1868 that of M.R.C.S. Eng. After taking the M.R.C.V.S. he obtained an appointment as lecturer at the Royal Agricultural College at Cirencester, but did not retain this for more than a year. He subsequently became a student at the London Hospital, where he was a dresser to Jonathan Hutchinson. This was the beginning of a close association with Hutchinson which terminated only upon the death of the latter a few months ago.

In 1867 or 1868 he began to work especially at ophthalmology, and became a clinical assistant to Hutchinson at Moorfields Hospital. In 1870 he obtained the F.R.C.S. In May, 1871, he was appointed curator of the museum and librarian at the Royal London Ophthalmic Hospital, and held this post for a little over two years. During his tenure of the curatorship he did excellent pathological work and published several papers of merit, notably those on the vascular supply of the retina and on the microscopic changes in embolism of the arteria centralis retinæ. This latter was one of the four earliest communications on this subject in which the clinical diagnosis was confirmed by the microscope. The "Curator's Report" in Vol. III. of the Ophthalmic Hospital Reports was probably the earliest of Nettleship's writings upon ophthalmic subjects, and the beginning of a very long list which has ended only with his death.

After a few years on the staff of the South London Ophthalmic Hospital (now rebuilt as the Royal Eye Hospital) Nettleship was, in 1878, elected ophthalmic surgeon to St. Thomas's Hospital, in succession to Liebreich. This post he filled with conspicuous ability until 1895, and his name is still cherished and honoured by those who were associated with him in the hospital and medical school. For a comparatively short time he was also ophthalmic surgeon to the Hospital for Sick Children, Great Ormond-street, and some of the abundant clinical material under his observation there formed part of a valuable paper on Forms of Congenital and Infantile Amblyopia published a few years later.

In 1882, to his gratification, he returned to Moorfields Hospital as assistant surgeon, and five years later was elected surgeon to the hospital. He remained on the active staff until 1898. On his retirement he presented a sum of money to the committee of the hospital for the purchase of instruments or apparatus for pathological and physiological investigations; this fund has proved of great utility.

Nettleship was one of the founders of the Ophthalmological Society of the United Kingdom in 1881, and was its first surgical secretary. He took a deep and active interest in the welfare of the society and contributed not a little to its success. Many of his most valuable papers are to be found in the Transactions of the society. In 1895 he was elected President of the society, and served this office for two years.

In 1902 he decided to retire from private practice and left London to live permanently at Hindhead, where he had spent week-ends and holidays for many years. This retirement from active practice was but the starting point of a period of renewed activity in scientific work. Freed from the routine of a large consulting and operative

practice, he devoted himself to the investigation of ophthalmological problems, and took up very energetically the subject of heredity. During the last ten years he has accomplished a prodigious amount of extremely valuable work upon heredity in diseases of the eye, albinism, and allied subjects, and has published a series of papers, including his Bowman lecture "Upon Some Hereditary Diseases of the Eye," which are monuments to his tireless industry and to his enthusiasm in research. In conjunction with Karl Pearson and C. H. Usher he had recently all but completed a large monograph upon "Albinism in Man" (one of the Drapers' Company Research Memoirs), of which the last part is to be published before the end of the year. In 1910 Mr. Nettleship was appointed a member of the Government's "Departmental Committee on Sight Tests." The report of this committee after two years of arduous work was published in 1912. He was throughout his life a strenuous and tireless worker, and his writings upon ophthalmic subjects are very numerous; they have been published chiefly in the Ophthalmic Hospital Reports and the Transactions of the Ophthalmological Society. It is a tribute to his ability, and to the punctilious care which he always observed in the preparation of material for publication, that there is scarcely a paper which even now will not repay perusal and which has not some permanent value.

The esteem and regard in which Nettleship was universally held by his pupils and colleagues found definite expression at the date of his retirement from practice. The fund then collected for the presentation of a testimonial was, in accordance with his own desire, devoted to the establishment of a medal "for the encouragement of scientific ophthalmic work." This prize is in the custody of the Ophthalmological Society and is awarded triennially. In 1909, to the great satisfaction of all, it was awarded to Nettleship himself in recognition of his researches upon heredity in diseases of the eye.

Mr. Nettleship married in 1869 Elizabeth Endacott, daughter of Mr. R. Whiteway, of Compton, Devon, but leaves no issue.

Mr. J. B. Lawford writes: "By the death of Edward Nettleship the followers of ophthalmology have lost a leader in that branch of medicine, and one whose life and work have added lustre to his profession. His professional reputation is so well established and so world-wide that no words of mine can enhance it, but as one who has had the privilege of a long and intimate association with him I desire to contribute my quota of admiration of his professional and personal characteristics. Nettleship was a man whose high ideals and sterling character, no less than his great ability, won the respect and admiration of all who were brought into immediate contact with him. He was an indefatigable worker and a highly trained observer, and he possessed in remarkable degree the genuine scientific spirit. In all his investigations upon whatever subject he was actuated by one, and only one, desire, which was to arrive at the truth; preconceived ideas were never allowed to influence him in his search. His work in ophthalmology, as in other branches of science, was characterised by punctilious and unremitting care, and he never spared time or trouble in his endeavour to render it thorough. It is difficult to say exactly wherein his great merit as a teacher lay. It seems to me now that it was less in the actual knowledge he imparted to his pupils than in his wonderful faculty of encouraging their powers of observation and of infecting them with his own enthusiasm for and thoroughness in investigation. It is safe to say that there are few, if any, of those who worked with or under him, who do not feel as deeply grateful for his example as a clinical investigator as for his precepts as a teacher. His published work covered almost the whole range of ophthalmic science, more especially from the clinical side, and has added largely to our knowledge. It seems probable that his reputation will live chiefly by the work (work of a very high standard of excellence) on heredity, which he has accomplished during the last 10 or 11 years. The value of these labours was recognised recently by his election to the Fellowship of the Royal Society. He was engaged upon work of this kind until laid aside by his last illness, and during that illness he was distressed by the thought that he had failed to complete it.

Of Mr. Nettleship's personal characteristics I find it difficult to write without seeming exaggeration. An unusually broad-minded man, of scrupulous integrity, incapable of a mean or ungenerous action, thoughtful and considerate of others, he was as much beloved by those who knew him well, as he was respected by those who had a less intimate acquaintance with him."

HENRY FRANKLIN PARSONS, M.D. LOND.,

LATE ASSISTANT MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

A WELL-KNOWN figure in the public health service has passed away in the person of Dr. Henry Franklin Parsons, who died on Oct. 29th at his residence in Croydon. He was a Somersetshire man, the son of the late Joshua Parsons, surgeon, of Frome, and was one of 13 children, several of whom displayed evidence of unusual mental attainments.

He was educated at St. Mary's, and after obtaining numerous honours in the University of London examinations obtained his degree of M.D. in 1870. From the first his bent was towards public health, and he obtained the appointments of medical officer of health to two urban and two rural districts in Yorkshire—i.e., Selby and Goole. These posts gave him the unusual advantages of studying sanitation in both country and town, and also the needs of a growing district, since the town of Goole was at that time developing from little more than a village to become an important seaport of nearly 20,000 population. With these advantages, aided by close study, he had no difficulty in obtaining the gold medal in the examination for the public health degree of the University of London in 1876, and also in the same year the D.P.H. of the University of Cambridge. Three years later, on account of the profound knowledge displayed in his reports on the sanitary circumstances of the districts in his charge, which were duly submitted to the Local Government Board, he was invited to become a medical inspector under that Board, and henceforward became successively Second Assistant Medical Officer and Assistant Medical Officer and Inspector for General Sanitary Purposes, finally retiring at the age limit two years ago. He was thus brought in contact with such men as the late Sir George Buchanan, the late Sir Richard Thorne Thorne, and Sir William Power, successive Medical Officers to the Local Government Board. By them he was inspired in his devotion to public health, and to them his profound and wide knowledge was of the greatest service. Parsons belonged to a class of men whom the rise of specialism has extinguished, men like the late Dr. Bristowe, Dr. Alfred Carpenter, and Dr. Frank Payne, who had a grasp of science in general as well as of medicine. Thus, Parsons perhaps had a wider knowledge of the geology and botany of these islands than most professors of these sciences, as well as of natural philosophy in its widest sense. In acquiring this knowledge he availed himself to the fullest extent of his constant travelling over the country in the course of his duties as an inspector. In this way, favoured by the possession of a marvellously retentive memory, he became literally a mine of information. Not only on public health but on almost any subject information was more quickly obtained by going to him than in seeking it in books. His knowledge of physics was really great; it enabled him to take up scientific inquiries, such as that which he made on disinfection, in a manner that would not have been possible for many medical men, however well equipped professionally in general or special lines.

During his long period of work in association with the Local Government Board Parsons brought out a number of reports on various subjects. Perhaps the most important were his two reports on the influenza epidemic of 1889–92. These embraced an account of the epidemic in all its aspects, and form a classic on the subject which will be referred to as long as this plague continues to exist. Of great importance also was his recent report on isolation hospitals, a subject in which he took great interest and on which he was the acknowledged authority. Important reforms with which he had much to do were the introduction of slop-closets, on which he wrote a special report, refuse destructors, and disinfecting apparatus. Slop-closets were a great improvement on the midden privy which they replaced at that time when water-supplies were generally inadequate, although at the present time, with recent improvements which have been general in the matter of water-supply, they are rarely needed. He was also greatly interested in the prevention of nuisance from the removal of

manure and refuse from towns into rural districts, and prepared a report on the subject. He reported on the manufacture of rag-flock and the possible spread of infectious disease by this or other products of woollen rags. He prepared a memorandum on the sanitary requirements of cemeteries, also on disinfection by heat. His great knowledge of geology caused his advice to be much sought after in questions of water-supply, and he reported on geological considerations in relation to public health and sanitary administration. Having been brought up in an agricultural district he was greatly interested in the housing and other conditions affecting the agricultural labourer. He was a Fellow of the Geological Society, and for two years in succession President of the Epidemiological Society of London. His presidential addresses, on Half a Century of Sanitary Progress and its Results, and on the Comparative Mortality of English Districts, were of great interest and dealt with wide problems. He also contributed papers on the Etiology of Diphtheria and on the Distribution of Mortality from Influenza.

Parsons was of retiring disposition and reserved in manner. He did not readily make friends, seeming at first to repulse all advances, especially in the case of non-professional acquaintances; yet he had a large circle of firm friends, to procure information for whom he would take endless trouble, while he was generous and good natured to an extreme degree. It may be said of Parsons that his function was to supply knowledge to his colleagues and to the whole of the sanitary services of the country. For this purpose he held conferences innumerable with representatives of sanitary authorities and with medical officers of health, both at the central office in Whitehall and in the provinces. In this way he probably influenced the sanitary development of this country more than anyone else, but he was consequently involved in a mass of routine work, which left no leisure for preparation of personal works, his whole time being devoted to the requirements of his department. Hence he was not associated with any great movement which would appeal to the public, and, as is unfortunately the usual case under these circumstances, he received no public recognition or honour.

He was hoping on his retirement, which took place two years ago, to write several works embodying the results of his profound experience, but this was not to be. Soon after this symptoms of new growth in one of the bones were followed by amputation of the leg. In an unfortunate fall he fractured the stump of the leg, and finally cerebral symptoms with coma, probably due to secondary growths, ensued. At the time of his death, however, he had completed a work on hospitals which is in the press, and had commenced other works. His wife died recently, but he leaves two daughters, who are married, and who were with him at the end.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. H. J. Garrigues, formerly a professor of midwifery in New York.—Dr. Baudon, formerly Deputy for the Oise.—Dr. E. Klebs, formerly professor of pathological anatomy in the University of Zürich.—Dr. B. Steuer, sanitary councillor, Berlin.

RURAL HOUSING IN THE COUNTY OF SOMERSET.—The medical officer of health of Somerset, Dr. W. G. Savage, in his annual report states that there is a shortage of houses throughout the whole county.

DONATIONS AND BEQUESTS.—The late Mrs. Caroline Conradine Sophia Dickinson, of Boscombe, has left by will £1000 to endow a "James Bathgate Dickinson" bed in Manchester Royal Infirmary, and £500 to endow a "James Bathgate Dickinson" cot in the Royal Victoria and West Hants Hospital, Bournemouth. Subject to other bequests the testatrix left a fund of £8180 16*s.* 6*d.* upon trust to provide four "James Bathgate Dickinson" scholarships for medical students at the Manchester Royal Infirmary and at Owens College, Manchester, one-fifth for a scholarship in anatomy, one-fifth for a scholarship in pathology, one-fifth for a research scholarship in surgery, and two-fifths for a research scholarship in medicine. Subject to sufficient residue she left £1800 upon trust as to one-half for a scholarship in chemistry, tenable at the Stalybridge Technical School, and as to one-half upon trust for Epsom College for purposes other than building as the governors decide upon.

Correspondence.

"Audi alteram partem."

MOONLIGHT AND DECAY.

To the Editor of THE LANCET.

SIR,—In reference to your interesting annotation under the above heading which appeared in THE LANCET of Oct. 25th, it is worth noting that the idea that moonlight brought about or assisted putrefaction is at least as old as Plutarch. In the last "problem" of the third book of the Convivial Questions[1] the story is told of how Euthydemus of Sunium entertained his friends with a large wild boar. When the guests expressed admiration at its size, Euthydemus replied that he had had another much bigger, but that being brought in from the country under the moon it had gone quite rotten, and he was absolutely at a loss to understand why this should happen; he should have thought that the sun being so much hotter than the moon would have made meat putrefy the sooner. Moschion, the physician, argued that putrefaction is a liquefaction of the flesh, and that putrefying bodies get moister and moister. Gentle heat stirs up the humours, but does not prevent them from working; a high degree of heat, on the other hand, dries up the flesh. Thus, the gentle heat of the moon promoted moisture and so putrefaction, while the sun by his heat shrivelled and drew out moisture from bodies.

Plutarch, however, argued that flesh putrefied more quickly in the summer when the sun was hot than in the winter when his beams were weaker, so that gentle heat could not be the cause of putrefaction. Personally, he should ascribe the effect of the moon to some quality proper to a "humour" transmitted from her, *'ιδιότητα μᾶλλον 'αιτιατέον τοῦ φερομένου 'ρεύματος 'απ' 'αυτῆς.* Plutarch presumably knew nothing of polarised light, but apparently his theory had a basis of truth in it.—I am, Sir, yours faithfully,

Westerham, Nov. 4th, 1913. H. P. CHOLMELEY.

CLAIMS AND CONSULTATIONS.

To the Editor of THE LANCET.

SIR,—Allow me to reply briefly to Dr. J. M. Clarke and Mr. M. Wilson on their remarks in THE LANCET of last week on the above subject. I am in full accord with Dr. Clarke that medical fees in medico-legal cases should be placed in the same position of safety as legal fees.

Mr. Wilson observes that I evade the question as to the legality of demanding a medical fee for being present when an examination is being made. I will be quite candid and acknowledge that I am not aware whether the matter has been ever decided in the courts. If the point has not been decided I am quite prepared to arrange for a test case to be brought forward.

We are living in very medico-legal times. The past seven years has seen the commercial success of the motor-car, the taxicab, and the motor-bus. "Running down" cases have become one of the features of the High and county courts. The Workmen's Compensation Act and the National Health Insurance Act have come into force during the same period. If the legal profession did not predominate so much in Parliament the interests of the medical profession might have been much better protected.

I am, Sir, yours faithfully,

Castle-court, E.C., Nov. 4th, 1913. J. J. SCANLAN.

THE VALUE OF THE TREATMENT BY "FIXATION ABSCESS."

To the Editor of THE LANCET.

SIR,—Having urged my colleague, Dr. de Lostalot, to publish some cases of treatment of infections by "fixation abscess," a paper you were good enough to publish in your issue of Oct. 18th, p. 1118, I send you herewith a short summary of a case of purulent bronchitis and pneumonia in which I have reason to think my patient's life was

[1] Teubner Ed. Moral. Plutarchi, vol. iv., p. 132.

probably saved as a result of that treatment. Mrs. X. aged 70, was taken ill at her residence last spring with an attack of influenza—a disease she is very susceptible to. This quickly developed into a bronchitis with the expectoration of much purulent matter. Between the fifth and sixth day definite signs of consolidation in the middle and posterior portion of the left lung appeared, a sufficiently grave symptom in a patient of her age taken alone. In spite of active treatment and excellent nursing more grave symptoms ensued within the next two days. Dr. de Lostalot kindly saw the case with me, and suggested that I should try the effect of a "fixation abscess," a treatment I had no experience of. Within an hour or so I therefore injected 2 c.c. of pure turpentine under the skin in the upper and outer third of the thigh.

On the third day a faint blush appeared over the site of the injection, and improvement in symptoms began from that time. On the fourth day the abscess was opened and treated with a Bier's cup, as described by Dr. de Lostalot in his paper referred to above, and within three or four more days my anxiety as to my patient's life had been removed and she made an excellent and fairly rapid recovery, and this in spite of two troublesome attacks of tachycardia, when her pulse ran away at 130 for from 12 to 18 hours, this latter curious symptom she having been occasionally subject to for many years.

Personally, I have no doubt of the remarkably good effect of the fixation abscess treatment in the above case, and I shall certainly immediately resort to the same simple remedy in any similar condition I may come across.

I am, Sir, yours faithfully,

Biarritz, Oct. 26th, 1913. DOUGLAS D. MALPAS, M.D. Aberd.

THE RESULTS OF "CONTAGIOUS DISEASES ACTS."

To the Editor of THE LANCET.

SIR,—Now that a Royal Commission has at last been appointed to inquire into the problems of venereal disease many thoughtful people are asking what steps can be taken to safeguard the public health in this direction. It is often assumed that the only possible methods are "the Continental system" (C.D. Acts), or compulsory notification, but comparatively few people seem to have much knowledge as to the results of these measures where they have been tried, or of the practical difficulties encountered. It may therefore be of interest to the general public to know that a society exists which for over 30 years has made a study of the methods of dealing with these diseases and cognate problems. The information obtained has been carefully scheduled and is open to those who desire to refer to it at the offices of the British branch of the International Federation for the Abolition of State Regulation of Vice, 19, Tothill-street, Westminster, London, S.W. The secretary is also prepared to deal with requests by post.

I am, Sir, yours faithfully,

HELEN WILSON, M.D. Lond.,

Osgathorpe Hills, Sheffield, Oct. 31st, 1913. Honorary Secretary.

EYESORES.

To the Editor of THE LANCET.

SIR,—To the twentieth anniversary dinner of the Scapa Society for the Prevention of Disfigurement in Town and Country Mr. James Bryce, lately British Ambassador to the United States, wrote:—

> Will you please convey to the members of Scapa my hearty congratulations on what they have accomplished, not only in rousing public sentiment here, but in setting an example which has told powerfully in America, where a similar movement for delivering rural beauty from the disfigurements of advertising has been steadily growing and has already achieved considerable success? Some public spirited men are organising a league of persons who are to pledge themselves not to deal with the disfigurers, and it seems that the advertisers are to be frightened into making their pictorial designs less hideous. This is at least an admission of the mischief now done.

Eighteen English counties have now by-laws made under the Act of 1907 in the following form:—

> No advertisement shall be exhibited on any hoarding, stand, or other erection visible from any public highway (whether carriageway, bridleway, or footway), and so placed as to disfigure the natural beauty of the landscape.

In the later cases erections visible from railways or open water are specifically included.

Many urban authorities have also obtained power to forbid disfiguring advertisements visible from parks and pleasure promenades, and similarly to protect certain scheduled "views." Several of these authorities have also power to prohibit in residential districts hoardings exceeding 12 feet in height. This is in addition to the regulations in force in many urban districts forbidding sky signs. The Act of 1907 does not give adequate powers for the defence of villages and rural scenes (other than the open country) and of cities and towns. A Bill bringing them within the pale of appropriate regulation is in charge of Captain the Hon. A. C. Murray, M.P., and will be introduced and pressed forward in the coming session. Meanwhile, as every discerning traveller is aware, the influence of many great landlords has been invoked and exercised to exclude disfiguring advertising from the areas under their control.

It is the deliberate policy of most of the directors of Garden City and Town Planning Associations to provide against the entry of the evil by restrictive covenants in all leases. The voluntary renunciation by great firms in the motoring and cycle trade of the practice of roadside advertising is an illustration of the willingness of the directors of industry to defer to public opinion. It is believed that when the existence of the means of remedy is known all classes of the community who find pleasure in travel—notably motorists, cyclists, photographers—will co-operate in inducing local authorities to take action. The society (25, Victoria-street, S.W.) is always ready to advise.

I am, Sir, yours faithfully,

RICHARDSON EVANS,

Westminster, S.W., Oct. 28th, 1913. Chairman of Committee.

THE IDENTITY OF DR. THOMAS SPENS.

To the Editor of THE LANCET.

SIR,—The informant to whom Dr. C. Edgar Lea refers in the last paragraph of his letter, entitled "The Spens (Stokes-Adams) Syndrome," has confused Nathaniel and Thomas Spens, father and son, not a very hard thing to do as I, the great-grand-nephew of the former, have found before now. Nathaniel Spens was Raeburn's Archer.

Nathaniel Spens was the third son of Thomas Spens, of Lathallan, Fifeshire. He was M.D. St. And., 1773; License of the R.C.P.E., 1773; Fellow, 1774; President, 1794. A fine bowman, he was a "Royal Archer," that is, one of the King's Bodyguard for Scotland. He was painted by Raeburn in this uniform, and it is supposed to be that artist's masterpiece.

Thomas Spens was the son of the above Nathaniel. He was M.D. Edin., 1784; License of R.C.P.E., 1787; Fellow, 1788; President, 1803. He died at his house, Drummond Place, Edinburgh, on May 27th, 1842, being in his 79th year, and treasurer of the College.

Nathaniel, the Archer-President, was thus a cadet of the ancient house of Spens of Lathallan, which is derived from a younger son of the ancient Earls of Fife. Sir Patrick Spens, of ballad fame, who was sent by Alexander III. of Scotland in 1281 to convey his daughter Margaret to Norway to marry Eric II. of Norway, was of this family. On his way home Sir Patrick and all his crew were drowned off Aberdour. Another Patrick Spens, a cadet of this family, went to France in 1450 as one of the 24 Scottish Archer Guards of Charles VII. of France, and founded the two baronial families of France, De Spens-Destignots, Seigneurs of Destignots and St. Germains, and De Spens-Destignots, Seigneurs De Lancre.—I am, Sir, yours faithfully,

T. GRAEME DICKSON, L.R.C.P. Edin., &c.

Buxton, Nov. 4th, 1913.

ROYAL FREE HOSPITAL.—At the last quarterly meeting of the committee of management of the Royal Free Hospital, Sir E. Durning Lawrence, Bart., in the chair, it was announced that satisfactory progress had been made in the construction of the new out-patient department, and hopes were expressed that this department will be opened during the first half of 1914. It was reported that negotiations had been proceeding for some months past for securing recognition of the hospital as a centre for the treatment of tuberculosis under Section 16 of the National Insurance Act.

THE NATIONAL INSURANCE ACT.

INSURANCE AND THE ETHICAL RELATIONS OF MEDICAL PRACTITIONER AND PATIENT.

IT is a subject of complaint on the part of Insurance Committees that certificates are sometimes granted by medical men to insured patients which do not state in sufficiently full terms the nature of the disease which is the cause of the inability to work. The question of what should and what should not be placed on a certificate is a very difficult one. In some instances a certificate containing merely the statement that its subject is unable to perform the duties of his employment has been accepted, and the medical profession can bring claims that such certificates should always be accepted. At a recent meeting of the Leeds Insurance Committee the suggestion was put forward that the medical man regarded the patient as his private patient and was loth to offend him by supplying information to third parties with regard to his illness; he, indeed, considered himself precluded by the rules of professional ethics from doing so without the patient's permission. It must be remembered that the initial certificate is given to the insured person himself and not to any third parties. But it is clear that the Insurance Act contemplates the acceptation by medical practitioners of service under circumstances which in the case of their private patients do not prevail, and to practitioners not used to the requirements of club practice the system of reporting upon their patients' diseases in any way which cannot remain confidential between doctor and patient must necessarily be repellent. There is, however, one broad aspect of panel practice which should not be lost sight of at this early stage of the practical working of the Act. Either the medical man must regard himself as working for the Insurance Committee under a contract made with it, or as working for his patients under contracts made for them through the Insurance Committee's agency, and it is submitted here with some emphasis that the medical profession should consider carefully before it claims to be in the second position indicated. Reference to the case mentioned in THE LANCET of Oct. 18th, p. 1159, of Titherington *v.* Dunlop will make the matter clearer. In that case a county court judge decided that a medical man on the panel was liable to a patient for the amount of fees paid to a second practitioner called in by the patient when the defendant did not respond to his summons. We have no doubt that before long an appeal upon this decision will be heard, and that the Divisional Court will be asked to say whether there is any contract between the practitioner and the patient under the Act such as will render the former directly liable to the latter for a breach of that contract. We pointed out the importance of the point raised, because in our opinion it involved the whole question of liability between medical man and patient arising out of alleged negligence, or any other supposed breach of duty. The principle that where there is no contract between two persons there is no duty which one of them can enforce against the other, may be taken to govern the matter, and the question who are the parties to the contract in insurance practice will be determined in this way. Considering that the medical men serving on the panel will be in a very unenviable position if they are liable to litigation at the suit of every patient attended by them, it becomes difficult to claim on the one hand direct responsibility to the Insurance Committee only, and on the other the same relations between practitioner and patient that exist in private practice.

THE KENSINGTON BOROUGH COUNCIL AND BACTERIOLOGICAL EXAMINATION ON BEHALF OF INSURED PATIENTS.

As we reported in THE LANCET last week (p. 1291), at a meeting of the London Insurance Committee on Oct. 23rd a motion by Dr. H. H. Mills to the following effect was unanimously carried:—

> That it be referred to the Medical Benefit Subcommittee to inquire and report as to the facilities for obtaining clinical investigations and treatment for insured persons at the metropolitan hospitals.

The public health committee of the borough of Kensington has now consented to supply to all the practitioners on the panel in the district outfits for the collection of material in cases of suspected phthisis, enteric fever, diphtheria, and venereal disease, and to pay out of the rates for bacteriological examinations. The examinations will be made at the Lister Institute. This is a recognition that insured persons have a claim upon the public health service of the country, and indicates also a direction by which the hospitals of different areas may be brought into close touch with insurance practice in a way that may be mutually advantageous. A writer in the *Times*, alluding to this very point, has recently suggested that "an ideal arrangement would be for the hospital to be the centre for each insurance area which every doctor should feel that he could use for consultative purposes. The hospital laboratory, equipped with all available scientific apparatus for the investigation of disease (X rays, &c.), should be at the service of the doctors, who should be encouraged to take their clinical material for examination. It is in every way desirable that the doctors should be personally interested in the investigation." The suggestion is a far-reaching one, and shows that the inquiry proposed by the London Insurance Committee may have great practical results if the hoped-for coöperation of the hospitals is realised. A conference between the hospitals and the London Committee should be easily brought about, and an interchange of views and information might lead to a systematic use by the practitioners on the panel of the facilities afforded by the hospitals for scientific research, alike to the great benefit of their patients and the raising of the standard of their work. There are many things to be arranged before this position is reached, and especially must the independence of the scientific work of the hospitals not be altered by the fact that any work done in their laboratories on behalf of the insured patients would be paid for out of the rates. The geographical distribution of hospitals is also not quite perfect for such a scheme. But these are details, not insuperable bars, and to evolve a comprehensive scheme despite such difficulties would be well within the powers of a broad-minded conference.

NON-PANEL SOCIETY IN ST. PANCRAS AND ISLINGTON.

On Oct. 31st a body of between 30 and 40 non-panel practitioners engaged in practice in St. Pancras and Islington met in the Midland Grand Hotel, and after a preliminary discussion proceeded to form a non-panel society for the combined area. The following office bearers were elected:—Dr. B. G. Morison, chairman; Dr. A. F. Shoyer, 101, Tollington Park, N., honorary secretary and treasurer; and Drs. A. Bousfield, C. G. Mack, and J. F. Paul (Islington), A. Brown, G. F. Glinn, and Maccarthy (St. Pancras) members of committee. Mr. Percy B. Spurgin, who was present as a visitor, strongly advocated the necessity of confederating all such non-panel societies and non-panel practitioners in the Non-Panel Medical League now being formed, which he anticipated would be of the greatest service to the profession in the inevitable conflicts that still awaited it.

A discussion then arose as to the position of members of this society with regard to the British Medical Association. It was generally agreed that precipitate resignations of membership were not desirable, and that efforts should be made to induce reform in the policy of the Association, which was strongly disapproved. The following resolution, moved by Mr. J. N. Glaister and seconded by Dr. A. Bousfield, was carried without a dissentient:—

> This meeting of non-panel practitioners of St. Pancras and Islington expresses its profound dissatisfaction with the manner in which the British Medical Association has persistently ignored the interests of non-panel practitioners.

PROVISIONAL REGULATIONS FOR PANEL COMMITTEES AND PHARMACEUTICAL COMMITTEES.

The National Health Insurance Joint Committee, acting with the English and Welsh Insurance Commissioners, have issued provisional regulations to come into force immediately to regulate the constitution, appointment, and duties of the Panel Committees and pharmaceutical committees which are to be formed under Sections 32 and 33 of the National Insurance Act, 1913. These rules are dated Oct. 27th, 1913, and are to be cited as the National Health Insurance (Panel and Pharmaceutical Committees) Regulations, 1913. There are 32 regulations and three schedules, price 1½*d*. They provide for the election as members of the Panel Committee of duly qualified medical

practitioners of whom not less than three-fourths shall be practitioners on the panel, the electors being practitioners on the panel. Nomination papers are to be asked for by Nov. 10th, 1913, and nominations are to be sent in by Nov. 20th. Modified forms of election to secure representation of each area in a county and alternative methods of appointment other than that provided for by the regulations may be sanctioned if application is made under the regulations before Nov. 20th. The above provide for the appointment of members of Panel Committees to hold office till July 15th, 1914, and schemes for subsequent elections may be submitted by Panel Committees before March 31st, 1914. The number of members to be appointed on each panel committee is fixed by a schedule. Regulations of a similar character are made for Pharmaceutical Committees, which are to consist as to at least two-thirds of each committee of registered pharmacists, and of which the membership is to be equal to one-fifth of the Insurance Committee of the county or county borough. A group of regulations affect both kinds of committee, one of these providing for the removal of a member who fails to attend three consecutive meetings of his committee. Regulation 32 specifically assigns to the Panel Committee the duty of making on behalf of the practitioners on the panel arrangements with the Insurance Committee for the distribution amongst practitioners on the panel of those insured persons who have failed to select a practitioner or have been refused by the practitioner whom they have selected.

MIDDLESEX INSURANCE COMMITTEE: PRIVATE CHARGES MADE TO INSURED PERSONS.

The Middlesex Insurance Committee on Nov. 3rd fixed Jan. 10th, 1914, as the date for the revision of the medical list. It was reported that 1018 applications for sanatorium benefit had been received to date, 714 being from men and 304 from women. A curiosity of insurance red tape came under notice in connexion with administration of sanatorium benefit. Although it had provided an insured person suffering from tuberculosis with an open-air shelter, the committee decided to inform the Brentford board of guardians, who wrote suggesting that the committee might have supplied a blanket "as an appliance to the shelter," that as its responsibility did not extend to the relief of distress it could not supply the blanket. On the consideration of the report of the Medical Service Subcommittee discussion arose as to charges to insurance patients. The subcommittee recommended that a practitioner be informed that the committee viewed with disapproval the practice of charging panel patients extra fees.

Mr. H. B. Brackenbury moved as an amendment the following words which actually appeared in the subcommittee's report:—

> That although the committee does not go so far as to say that in no case can an insured person make a private arrangement with a doctor on the panel for payment of some extra fees, it is of opinion that the practice is to be deprecated.

Mr. Brackenbury urged that although there should be no extra charges within the insurance contract, the agreement did not cover every conceivable set of circumstances; in fact, there were circumstances which were expressly excluded by the Act. Occasions sometimes arose when both doctor and patient felt that the circumstances did not come within the insurance contract.

Various members of the committee declared that in no circumstances should extra charges be permitted. On a division only four voted for the amendment, and the recommendation of the subcommittee was approved.

WORCESTERSHIRE INSURANCE COMMITTEE: PRIVATE CHARGES MADE TO INSURED PERSONS.

At a recent meeting of the Worcestershire Insurance Committee, Mr. Willis Bund presiding, a discussion took place on the same point as had engaged the Middlesex Insurance Committee. It appeared that complaints had been received as to panel practitioners charging insured persons for medical attendance and medicines. The General Purposes Committee reported that the County Medical Committee had passed the following resolution:—

> That practitioners on the panel shall discontinue to accept any contract payments from insured persons.

The subcommittee recommended that this be accepted in good faith, and on the understanding that there should be no suggestion of payment on the part of the practitioners or any pressure brought to bear, so that any payment made by an insured person to his panel doctor should be absolutely voluntary.

Dr. C. L. Hawkins objected to the insertion of the words "in good faith" as casting a slur on the medical profession. Dr. H. E. Dixey seconded the deletion of the words.

Mr. G. W. Hobson said there were reasons for the insertion of the words, but he was not going to discuss them in the presence of the press. He hoped the committee would adhere to the paragraph.

Dr. H. E. Moore said the Medical Committee intended that the profession throughout the county should stick to the resolution passed. If the committee obtained precise information showing that any doctor was trying to make insured persons pay for medical attendance against their will, the Insurance Committee would in their action have the full support of the Medical Committee. The charges, however, had never been substantiated. They were told that people would not come forward for fear of intimidation. Charges of this nature, reflecting on the honour of professional gentlemen, should be substantiated, if not they should be quashed at once.

Mr. T. W. Parkes thought the matter should go back to the committee. The doctors had laid themselves open to these charges because of their attitude towards public appointments. The Worcester county council had been boycotted, and Mr. H. C. Gardner and himself had been browbeaten in their own homes by a Worcester doctor. They were not, however, just the sort of public men who would take knocking in that way. There were two sides to the question.

Mr. Brewster said he regretted he was not able to bring forward any names of persons who made complaints. He was positive it could be borne out by several members from Kidderminster that the charges were correct.

Dr. Moore: Do you still say before this committee that doctors are charging insured persons contract rates against their will?

The Chairman: He does not say that. What is said is that certain doctors have asked patients, "Are you subscribing to my club? Because, if so, there is no need for you to go to the chemist for your medicine." If they subscribed to his club he would give them the medicine.

Eleven voted for the deletion of the words "in good faith" and 21 against. The paragraph was then approved.

THE POSITION OF HERBALISTS UNDER THE NATIONAL INSURANCE ACT: THE ACTION OF WORCESTER CITY.

In Worcestershire the County Insurance Committee have decided not to grant the application of insured persons to make their own arrangements with a herbalist, but the Worcester City Committee have twice, after long debate, decided to grant such applications. They did so at a recent meeting despite an earnest appeal by Mr. S. Wellesley Coombs, who presented a strong case against such permission. There were three applications before the meeting, and the committee granted them by 15 votes to 9.

In the course of the debate Dr. H. Neville Crowe asked what answer the applicants had given to the question: "By what doctor do you desire to be attended?" and the Chairman said they had replied, "Mr. Burden, Bridge-street," adding that "the point was not important, as the herbalists might call themselves herbal doctors," when Dr. G. W. Crowe pointed out that if herbalists called themselves doctors they would be liable to a penalty under the Medical Acts.

Dr. Neville Crowe moved as an amendment to a motion that the application should be granted for those persons to make their own arrangements, that "those arrangements should not be with any person not qualified and registered under the Medical Act of 1858." The Chairman did not think that the Committee would be entitled to pass that amendment, which he said was contrary to the spirit of the Act.

Mr. Coombs then proposed that the matter be referred back to the committee, with an instruction to allow the applicants to make such arrangements only with a duly qualified medical practitioner, and in a reasoned speech explained why medical men must oppose such applications. The doctors, he said, would fight the question impersonally; it was entirely a matter of principle. He maintained

that the Act and the Regulations contemplated throughout that the insured patients would only be treated by qualified registered medical men. If they receded from that point they would be going back 100 or 200 years to the days when there were no qualified persons. Referring to the case of emergency, he said no one but a highly trained doctor could detect the earliest signs of diphtheria, smallpox, or anthrax, and in such cases it was imperative that there should be swift and resolute action. It would be impossible for a medical man—say, the medical officer of health—to coöperate with an unqualified person in treatment of tuberculosis. Further, it was illegal for an unqualified man to prescribe, and if the Insurance Committee allowed such a person to prescribe they would be conniving at an illegality. The Government would not allow paupers to be treated by unqualified persons. He maintained that treatment by herbalists could not be "of the nature, quality, and extent not inferior to that under the arrangements made by the Insurance Committee." Whatever was the result of that debate he was glad to be able to relieve his conscience on that point.

Mr. Morris urged that the responsibility could not be said to rest upon the committee, inasmuch as those applicants said that whatever was the decision of the committee they would still go to the herbalist.

The Chairman said his personal opinion was contrary to the applicants', but he thought that as they had faith in herbalism they were entitled to receive that treatment. The applications were granted by 15 votes to 9, the four medical practitioners present being supported by five members of the committee.

THE DEATH OF DR. HORACE DIMOCK.

The tragic death occurred last week of Dr. Horace Dimock in circumstances which, as far as they have been elucidated, have been so freely published that they require no repetition. Dr. Dimock a few days before his death had appeared before the Wisbech magistrates on a charge of criminal libel, information having been laid before the bench by Mr. H. C. Meacock, chairman of the Isle of Ely Division of the British Medical Association. Arising out of this fact the funeral of Dr. Dimock, who was a native of the district, was made the occasion of reprehensible attacks upon the houses of Mr. Meacock and another medical man in the town of Wisbech. The whole story is very distressing.

Mr. Henry Meacock has sent to us for publication a statement, which has appeared substantially in the *Daily Mail*. It is accompanied by a reprint of a letter from Professor Sims Woodhead to the same journal, in which Professor Woodhead, in grave and forcible terms, begs that judgment may be suspended until a thorough inquiry has been held, inasmuch as "the Wisbech doctors, who are accused of persecuting the late Dr. Dimock, have themselves been subject to the foulest slander."

Mr. Meacock in his statement denies categorically that the late Dr. Dimock had been subjected to the boycott or persecution alleged, and asserts that libellous, and in some cases indecent, communications recently received by certain Wisbech medical men, had been traced upon evidence of the strongest possible nature to Dr. Dimock. Mr. Meacock states that the filthy nature of the communications made action necessary in the interests of the honour of medical men and of defenceless women, and that such action had been taken under the guidance of the police throughout. The statement reached us too late for publication in full.

A meeting of the Isle of Ely Insurance Committee to discuss the matter takes place too late for notice in this issue of THE LANCET.

THE second annual dinner of the Beit Memorial Fellows took place at the Trocadéro Restaurant on Oct. 31st, Dr. F. W. Edridge-Green being in the chair. Mr. Otto Beit and Sir James Kingston Fowler were guests on the occasion.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: JACKSONIAN PRIZE.—The subject for the Jacksonian Prize for the ensuing year, 1914, is the Pathology, Diagnosis, and Treatment of Trigeminal Neuralgia. Dissertations for this prize must be delivered at the College by Dec. 31st, 1914. Dissertations for the Jacksonian Prize for the present year, 1913, must be delivered at the College not later than 4 P.M. on Dec. 31st next.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle*: Dr. Eugen Ludwig has been recognised as *privat-docent* of Anatomy.—*Berlin*: The title of Professor has been conferred on the following gentlemen who have distinguished themselves in the struggle against tuberculosis but who are not on the teaching staff of the University: Dr. Alfred Bruck, secretary of the Hohenlychen Sanatoria; Dr. Paul Friedrich Köhler, physician to the Sanatorium at Werden-on-the-Ruhr and editor of the Annual Report on Tuberculosis Research; Dr. Otto Ernst Roepke, physician to the Railway Sanatorium near Cassel and editor of several tuberculosis reports, one of which appears in seven languages.—*Naples*: Dr. Giuseppe Palazzo has been recognised as *privat-docent* of External Pathology; and Dr. Camillo Pellegrino as *privat-docent* of Orthopædics.—*Rome*: Dr. Carlo Brunetti has been recognised as *privat-docent* of External Pathology; and Dr. Silvio Settimi as *privat-docent* of Odontology.—*Sienna*: Dr. Luigi Guerra-Coppioli has been recognised as *privat-docent* of Internal Pathology.—*Vienna*: Dr. Erich Ruttin has been recognised as *privat-docent* of Otiatry.

CANCER PRECAUTIONS IN PORTSMOUTH.—A new procedure for securing the earlier surgical treatment of those suffering from cancer was adopted by the Portsmouth town council at their meeting on Oct. 28th. The health committee, after consultation with the medical officer of health, recommended that information should be given to the public by which the disease might be identified. For this purpose it was suggested that a meeting should be called to which the nurses of the town and ladies interested in social, medical, and charitable work should be invited, when an address should be given by a surgeon who was a member of the town council, and that provision should be made for the microscopical examination of material in connexion with cancer free of charge. After a discussion, in which it was argued that such a procedure was likely to frighten people and do more harm than good, the report was adopted.

SIXTH INTERNATIONAL DENTAL CONGRESS.—At this Congress, to be held in London from August 3rd to 8th, 1914, under the patronage of H.M. the King, there will be an International Congress Museum, comprising the following sections:—1. Dental Anatomy, Histology, and Physiology. 2. Dental Pathology and Bacteriology. 3. Dental Surgery and Therapeutics. 4. Dental Physics, Chemistry, Radiography, and Metallurgy. 5. Dental Prosthesis. 6. Orthodontics. 7. Oral Surgery and Surgical Prosthesis. 8. Anæsthesia. 9. Oral Hygiene, Public Instruction, and Public Dental Services. 10. Dental Education. The officers consist of the chairman, Mr. A. Hopewell-Smith; the honorary general secretary, Mr. F. N. Doubleday; and eight other honorary curators. It is intended that the museum shall be an international collection of objects of interest, and be representative of every section of the Congress. Its nature and scope include the following:—

1. Specimens showing the evolution of tooth forms and of the dentition of man, with histological preparations bearing upon recent research, and exhibits illustrating the chemical composition and physiological action of the saliva.
2. Specimens of morbid conditions of the teeth, palate, gums, and jaws, photomicrographs and cultures of oral micro-organisms, and new bacteriological apparatus and appliances.
3. Specimens and slides of teeth, gums, and jaws affected by pyorrhœa alveolaris. Exhibits of various new methods of "inlaying" cavities and of "crowning" teeth.
4. Radiographs of the normal and diseased dental tissues.
5. Exhibits of various kinds of articulators, and specimens showing the various methods of "pressure casting" and the modern forms of continuous-gum work.
6. Models showing abnormalities in position of the teeth and appliances for their correction.
7. Specimens illustrating methods of dealing with surgical conditions of the teeth and jaws, including cleft palate, harelip, fracture and resection of the jaws.
8. Specimens illustrating the history and evolution of anæsthesia.
9. Photographs, charts, diagrams, specimens, and statistics of school clinics, and methods for the instruction of the public in the principles of oral hygiene.
10. Instruction forms, charts, diagrams, specimens, and demonstration models used in relation to dental education.
11. Historical objects of interest, such as books, instruments, and pictures.

Regulations and application and entry forms for intending exhibitors may be obtained on application to Mr. A.

Hopewell-Smith at the International Dental Congress Office, 19, Hanover-square, London, W., who earnestly invites the coöperation of all in making the Museum and the Congress a memorable success.

PENZANCE BOARD OF GUARDIANS AND THE DENTAL TREATMENT OF CHILDREN.—The Local Government Board has sanctioned the appointment of Mr. W. D. Motton, L.D.S. Eng., for one year as dental surgeon to the children at the Penzance workhouse, the remuneration to be by fees as arranged by the guardians.

KING'S COLLEGE HOSPITAL.—The out-patient department and a portion of the wards of the new King's College Hospital at Denmark Hill will be opened for the reception of patients on Monday, Nov. 10th.

THE annual festival dinner of the West Ham and Eastern General Hospital will be held at the Hamilton Hall, Liverpool-street Hotel, on Thursday, Nov. 20th, at 7.30 P.M., when the chair will be taken by Mr. Lionel A. Martin.

INVITATIONS have been issued by the Master and Wardens of the Society of Apothecaries to the annual dinner in the Society's Hall, Blackfriars, E.C., on Friday, Nov. 28th, at 7 o'clock, to meet the Lord Mayor and Sheriffs of London.

TAUNTON MEDICAL CHARITIES.—As the result of a carnival recently held in Taunton the sum of £100 has been given to the Taunton and Somerset Hospital, £75 to the Taunton District Nursing Association, £30 to the Bristol Eye Hospital, and £18 to some smaller Taunton medical charities.

LITERARY INTELLIGENCE.—The publication of a "Text-book of Medical Entomology," by Walter Scott Patton, M.B. Edin., I.M.S., of the King Institute of Preventive Medicine, Guindy, Madras, and Francis William Cragg, M.D. Edin., I.M.S., of the Central Research Institute, Kasauli, Punjab with 89 full-page plates, is announced by the Christian Literature Society for India, whose English address is 35, John-street, Bedford-row, London. The price of the book is 1 guinea net, or in India Rs.15. 12 net.

THE LATE MR. WALTER WHITEHEAD.—Mr. Henry Whitehead has bought a site in Bury for the erection of a clock tower over 50 feet high in memory of his brother, Walter Whitehead, who was a native of the town of Bury. It was the duty of the mayor, Alderman J. Parks, to convey the notice of the gift to the town council, which duly accepted it. Mr. Parks and the late Walter Whitehead were fellow students, and when Whitehead commenced practice in 1866—at Mansfield Woodhouse, Nottinghamshire, Mr. Parks assisted the young surgeon at some of his operations.

THE LADIES' GUILD OF ST. THOMAS'S HOSPITAL.—The ninth annual meeting of this guild was held in the Governors' Hall of St. Thomas's Hospital on Nov. 4th. The Countess Beauchamp presided, and there were present over 250 members and friends. Mrs. H. B. Irving gave a delightful address, and the honorary secretary, Mrs. Battle, presented a very satisfactory report, which, together with the financial report presented by Miss South, the honorary treasurer, tended to show that the guild was very prosperous and had done most excellent work. It had provided this year 2973 garments, more than half of which had been given to patients going to convalescent homes and who lacked the necessary outfit; the rest of the garments were for use in the wards of the hospital. Last year's deficit of £10 had been covered, but there was only a balance of 4*s.* 11*d.* to carry forward to the next year's accounts, and the committee would welcome new members and subscribers to help to carry on the work. The following officers and members of the executive committee were elected for the following year:—Chairman of Committee: Mrs. Ballance. Committee: Mrs. Belfrage, Mrs. Burrell, Mrs. Corner, Mrs. Hayward, Miss G. Lawford, and Mrs. Z. Mennell. Permanent Member of Committee: Miss Lloyd Hill, matron of St. Thomas's Hospital. Honorary Secretary: Mrs. Battle. Honorary Treasurer: Miss South. Honorary Work Secretary: Miss Clerk. Mr. Wainwright expressed his gratitude as treasurer of the hospital to the members of the guild, whose work helped so greatly to increase the comfort and well-being of the patients and to add to the efficiency of the hospital. After the meeting many members and their friends visited the wards of the hospital.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BROWN, A. E., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at University College Hospital.

COHEN, BERTRAM, M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Medical Officer to the Victoria Cottage Hospital, Sidmouth.

CORBIN, H. E., M.R.C.S., L.R.C.P. Lond., D.P.H. R.C.P.S., has been appointed Health Officer for Calcutta.

COURT, A. C. S., M.D., B.S. Edin., has been appointed Casualty Surgical Officer at University College Hospital.

BIRTHS.

HENDERSON.—On Oct. 29th, at Rodney-street, Liverpool, the wife of Dr. W. Savile Henderson, of a son.

MARRIAGES.

MERCIER—MACDOUGALL.—On Oct. 29th, at St. Pancras Church, London, Charles Arthur Mercier, M.D., F.R.C.P., F.R.C.S., of Parkstone, Dorset, to Mary MacDougall, youngest daughter of the late Donald MacDougall, of Glasgow.

STRUTHERS—BURGESS.—On Nov. 1st, at St. Jude's, Birmingham, by the Rev. Lester Pinchard, J. A. Struthers, M.B., Ch.B., of Stanley-road, Bootle, to Jean, daughter of the late James Burgess, Macclesfield.

DEATHS.

NETTLESHIP.—On Oct. 30th, at Longdown Hollow, Hindhead, Edward Nettleship, F.R.S., F.R.C.S., aged 68 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE HEALTH OF SIERRA LEONE.

A REPORT on the Colony of Sierra Leone for the year 1912, prepared by Mr. A. C. Hollis, C.M.G., has been issued. It gives the population of the colony as 75,572 (41,001 males and 34,571 females), and estimates the population of the Protectorate at 1,327,560, of whom 1,323,151 are natives other than those in military barracks, the remainder, 3426, being non-natives. The European residents in the colony and Protectorate number, as nearly as can be ascertained, 803, including 389 military and 230 officials. In the colony the birth-rate and death-rate for the year were both 17 per 1000. In Freetown, the capital, which has a population of 34,090, the birth-rate was 17 and the death-rate 22 per 1000. The seven chief causes of death were in order given as follows: (1) Diseases of the circulatory system; (2) diseases of the digestive system; (3) diseases of the respiratory system; (4) diseases of the urinary system; (5) debility; (6) malaria; and (7) blackwater fever. Only about 25 per cent. of the deaths registered were certified to by medical practitioners. The general health of the European population continued to be fair during 1912. Eleven deaths of Europeans were assigned to the following causes: Blackwater fever, 2; malaria, dysentery, hæmorrhage into stomach, strychnine poisoning, cardiac failure, cardiac failure and heatstroke, malarial alcoholism, cerebral malaria, and general debility and diarrhœa, 1 each. Ninety-eight European officials were placed on the sick list, the average number of days for each patient being 5·72. There was no case of yellow fever during the year and no epidemic of small-pox. Three cases of trypanosomiasis were reported from the Protectorate dispensaries; 2363 cases of malaria were treated, as compared with 2208 in 1911. Vaccination was carried on as usual both in the colony and in the Protectorate; 10,298 persons were vaccinated—83 per cent. with known success. In 1912 the number of in-patients at the various Government hospitals and dispensaries was 2716, and of out-patients 83,082. 316 operations were performed in the Colonial Hospital, Freetown; of these, 294 were successful; 2 patients were not relieved, and 9 died. Twelve cases of leprosy were under treatment; 6 of the patients died and 3 absconded, leaving 3 in the leper ward on Dec. 31st, 1912. Presentation swords and certificates have, as usual, been awarded to those native chiefs whose zeal in promoting the sanitary condition of their chiefdoms has appeared to merit recognition, and the interests of sanitation were appreciably advanced in 1912 both in the colony and in the Protectorate. In Freetown the extended gratuitous distribution of quinine, first instituted in 1911, was carried on successfully. The number of destroyed rats brought to the Colonial Hospital, and paid for at the rate of 1*d.* each, amounted to 2400. At Freetown in 1912 the mean shade temperature was 80·7° F., the highest point recorded being 99·2° in March and the lowest 62·2° in November. The rainfall measured 130·07 inches, as compared with 146·59 inches in 1911.

THE CASE OF MR. H. T. HAMILTON.

To the Editor of THE LANCET.

SIR,—The donations already acknowledged amount to £52 3*s.*, to which I have now to add the following: Dr. Abernethy, Barnes, £2 2*s.*

I am, Sir, yours faithfully,

W. H. GIMBLETT, M.D.

86, Sutherland-avenue, Maida Vale, W., Nov. 4th, 1913.

THE ANNALS OF SYPHILIS.

William Wadd, who was surgeon-extraordinary to George III., made a small collection of racy memoirs, among which are several curious historical naratives concerning syphilis. He mentions the suggestion of a facetious writer of the sixteenth century that the disease is of great antiquity; for, "whether, with physicians," says he, "we call it Lues Venerea, with 'pothecaries, the Venereal Disease, with ladies, the French Distemper, or with fine gentlemen, by that short name so commonly used in the time of Congreve and Wycherley, I am persuaded that it is as old as the days of Hercules." Be that as it may, Wadd says that it did not appear in Europe till the reign of Henry VII. Twelve years after the reign of that monarch had begun a proclamation was issued at Edinburgh, commanding all persons afflicted with "a contagious sikness, callit the grand gore that they pass forth and compair upon the Sandis of Leith, at ten hours before none; and thair sall have and find botis redie in the Haven, ordainit to them be officians of this burgh, reddelie furnisht with victuals, to have them to the Inch (Inch Keith) there to remain quhill God provyde for their health." They were transported there, says Wadd, "ne quid detrimenti respublica caperet"—a tolerably strong proof of the then virulence of the disease. So infectious was the disease considered, that one of the articles of accusation brought by the peers against Wolsey in the thirtieth year of the reign of Henry VIII. was, that "Knowing himself to have the foul contagious disease ..... he came daily to your Highness, rowning in your ear, and blowing upon your most noble grace, with his perilous and infectious breath." One of the first who appeared with a specific was Thomas Glanfield, who in the reign of Edward VI. acquired great fame by introducing guaiacum as a remedy. Jacob Berenger shortly afterwards treated the disease by mercurial ointment. It is recorded that his success procured him so much fame and money that he grew insolent and answered in a most contemptuous manner the Pope and the King of Spain, who had graciously invited him to practise at their courts. Some interesting references to the history of the disease are to be found in a book on the "Diseases of Tradesmen," by Bern. Ramazzini, professor of physic at Padua. In the English edition of this treatise, which was published in 1705, it is stated that "as soon as the dismal plague of the Pox flew from the siege of Naples all over Italy, and run from thence like lightning to all the parts of Europe, the chief and principal remedy they found out for controuling the fierce contagion was mercury; and to this very day the same remedy is still in vogue, being further recommended by the continued experience of two ages." Ramazzini goes on to say that the ancient physicians had observed that nothing was more effectual than mercury against the "wild running scab or itch," so that by analogy it was concluded that "since pocky persons had bloches and ulcers in their skin, mercury must likewise be of use to them, and experience justified the inference." Ramazzini also mentions James Berengarius, commonly called Carpus from his country, as the first author of the mercurial inunction. He was, says the professor of Padua, "the most noted surgeon and anatomist of those times; witness his works, from which, as being very rare and hard to come at, the modern anatomists have culled a great many important things without mentioning his name." Ramazzini further remarks that "Fallopius, in his treatise of the Pox, tells you that Jacobus Carpensis got above 50,000 Ducats of Gold only by curing the Pox with inunction; and that he killed many, tho' he cured the greatest part. For a certainty, this anointer knew better than the alchymists how to make a true metamorphosis of mercury into gold; a happyness sure that's very uncommon and far diffirent from what appears in the times we live in, which struck even Sennectus himself with admiration."

SO-CALLED RITUAL MURDER.

To the Editor of THE LANCET.

SIR,—The following extract from "Popular Errors," by John Timbs, published in 1841, may be of interest to your readers in connexion with the above subject:—

"One of the causes of the persecution of the Jews arose from a notion that they killed the children of Christians in order to use their blood in medicine. Gower, in his second book 'De Confessione Amantis' (first printed by Caxton), states it to have been prescribed to Constantine for the cure of his leprosy, but that he refused to try the medicine, and for that piety was miraculously healed:

> 'Thei would him bathe in childes bloode,
> Within seven winters' age,
> For as thei sayen, that shulde assuage
> The lepre.'

The Jews have likewise been charged with using human blood as an ingredient of the food compounded for the Passover festival. This abominable charge was revived in the year 1840, and gave rise to the disgraceful persecution of certain Jews at Damascus; but, for the honour of humanity, the atrocious accusation has been satisfactorily refuted and proved altogether groundless.

Mr. Salomons, who wrote a small volume upon this painful subject ('An Account of the Recent Persecutions of the Jews at Damascus,' by D. Salomons, Esq., 1840), argued that—

'The strict injunction against the use of blood in food is ever regarded as one of the highest importance by those who adhere to the principles of the Jewish religion. Were it possible to imagine for a moment that the Jew could be so lost to every feeling of nature as to engage in a murder for the attainment of any ordinary purpose whatever, it may be safely asserted that, dependent as the Jews are entirely on their religious teachers, it would be an entire violation of all their principles to interfere in any matter connected with religious objects without the express direction of their rabbinical authorities. The remark, therefore, lightly made, that superstitious, fanatical Jews may, in a spirit of Eastern bigotry, do what other persons of the same faith, but not imbued with the same sentiments, would hesitate to commit, is quite fallacious. A total ignorance of the nature and structure of the Jewish religion is exhibited by those who make this observation.'"

I am, Sir, yours faithfully,

London, Nov. 1st, 1913. A GENTILE.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Sir William Crookes, O.M.: The Preparation of Eye-preserving Glass for Spectacles.—Mr. A. W. Porter: On an Inversion Point for Liquid Carbon-dioxide in Regard to the Joule-Thomson Effect.—Mr. A. W. Porter and Mr. F. W. Edridge-Green: Negative After-images and Successive Contrast with Pure Spectral Colours.—Prof. O. W. Richardson: The Positive Ions from Hot Metals.—Mr. G. W. Walker: (1) The Diurnal Variation of Terrestrial Magnetism; (2) A Suggestion as to the Origin of Black Body Radiation.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF SURGERY (Hon. Secretaries—John Murray, Raymond Johnson): at 5.30 P.M.

Adjourned Discussion:
On Mr. Frank Kidd's paper on Pyeloradiography.

The following will take part in the discussion:—Mr. Gilbert Scott, Mr. Thomson Walker, Mr. John Pardoe, Mr. Ralph Thompson, Mr. A. E. Johnson, and others.

WEDNESDAY.

SECTION OF SURGERY: SUB-SECTION OF PROCTOLOGY (Hon. Secretary: P. Lockhart Mummery): at 5.30 P.M.

Mr. Aslett Baldwin: (1) Notes of a Case of Round-celled Sarcoma of the Rectum with Microscopic and Macroscopic Specimens; (2) Notes of a Case of Recto-uterine Fistula.
Mr. Lockhart Mummery: Case of Hæmorrhagic Proctitis.

Specimens:
(1) Hyperplastic Tuberculosis of the Colon.
(2) Cancer of the Sigmoid.

Papers:
Mr. Sampson Handley: A New Method of Administering Saline after Abdomino-perineal Excision of the Rectum.
Mr. Lockhart Mummery: Hæmorrhagic Proctitis, with cases.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries—W. Essex Wynter, Thomas H. Kellock): at 8.30 P.M.

Cases:
Dr. F. Parkes Weber: (1) Rheumatic Nodules (Rheumatismus nodosus of German authors) Associated with Rheumatic Torticollis; (2) Angiokeratoma with Bony Changes.
Mr. W. J. Midelton: Arthritis Deformans Treated with Continuous Counter-irritation.

(Washington, D.C.).—International Congress of Americanists.

(Paris).—Fourth International Medical Congress on Industrial Accidents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial Staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An Address
ON
THE DEGENERATION OF THE NEURONE IN THE LIGHT OF RECENT RESEARCH,
ESPECIALLY IN RELATION TO SYPHILIS AND GENERAL PARALYSIS.

Delivered at Birmingham at the Inaugural Meeting of the Midland Medical Society, Session 1913-1914,

BY F. W. MOTT, M.D. LOND., F.R.C.P. LOND., F.R.S.,
PATHOLOGIST TO THE LONDON COUNTY ASYLUMS.

MR. PRESIDENT AND GENTLEMEN,—Allow me to thank you for inviting me to follow the long list of distinguished members of our profession who have had the honour of giving an address at the annual inaugural meeting of the Midland Medical Society. I must first ask your permission to extend the title of my address in order to limit the scope to a subject in which I have long been interested—viz., the relation of syphilis to the degeneration of the neurone, especially in general paralysis, which owing to recent discoveries and the importance of the subject, particularly at the present time, necessitates a fuller discussion than other causes of degeneration of the neurone.

DEGENERATIONS OF THE NEURONE.

The term "neurone" implies a nervous unit—that is, a nerve cell and all its branches. The nervous system is made up of countless millions of nervous units, each one existing as an independent organism in contiguity but not in continuity. The neurones are genetically and trophically independent cellular organisms arranged in functionally correlated systems, communities, and constellations. There are two types of neurones, one in which the axis-cylinder process leaves the grey matter and acquires a medullated sheath—this is the first type of Golgi; the other, the second type of Golgi, in which the axis-cylinder process does not leave the grey matter. The nutrient and supporting tissues—viz., the blood-vessels, lymphatics, and neuroglia tissue—make up the histological elements.

Degeneration of the neurone may occur from an inherent lack of durability of certain correlated functional systems, as occurs in certain diseases which affect members of families at the same age in life and often in generation after generation—e.g., Huntington's chorea, hereditary ataxy. Degeneration of the neurone may result from direct injury or local extension of inflammation or by ischæmic softening due to obstruction of the blood supply by vascular occlusion; the degeneration that results therefrom is secondary. But when for whatever cause nervous tissue disappears the neuroglia always reacts by a nuclear and fibrillar proliferation—a law formulated by Weigert in 1890. The replacement of the nervous tissue by the neuroglia tissue causes a "sclerosis." But it is hardly necessary to remind you that the term "sclerosis" in the sense of a neuroglia proliferation being the primary cause is incorrect; the sclerosis is the effect, not the cause. Certainly there is a primary gliosis due to embryonic tissue taking on active growth, but the destruction of the neurones in syringomyelia is not caused so much by the gliosis as by hæmorrhages occurring in the glial tissue.

Now we recognise a certain number of primary degenerations of the nervous system characterised by insidious onset, progressive character, and a tendency sooner or later to a fatal termination, generally hastened by intercurrent disease or secondary microbial infections due to complications. I will put on the screen a slide to illustrate some of these primary degenerations. A pure primary decay of the neurone has been termed by Sir William Gowers "abiotrophy." Many of these conditions of abiotrophy are associated with chronic inflammatory changes, and it is very difficult to say how far these cause the decay of the neurone or are the result of it; certainly a proliferation of neuroglia tissue may result from simple atrophy and decay of the neurones, but a perivascular lymphatic infiltration with lymphocytes and plasma cells are evidence of a reaction to the poison.

Now there are two diseases which I have studied for many years in which this perivascular cell infiltration, together with neurolgia proliferation, is particularly marked and more or less universal in the central nervous system. They are the diseases caused by two specific protozoal organisms—the trypanosoma gambiense, the organism which causes sleeping sickness, and the spirochæte pallidum, the organism of syphilis.

Sleeping Sickness.

When I first published an account of the histology of sleeping sickness 14 years ago I pointed out the close similarity in the histological changes of the central nervous system to syphilitic meningo-encephalitis. I will show you now on the screen slides illustrating this, also one of experimental sleeping sickness. You will observe that the same perivascular infiltration with lymphocytes and plasma cells occurs in sleeping sickness, in syphilitic meningo-encephalitis, and in general paralysis of the insane (Figs. 5 to 9). In the last-named disease we have, as Noguchi says, a parenchymatous meningo-encephalitis.

The knowledge of the cause of sleeping sickness began with the discovery by Castellani of the trypanosoma gambiense in the cerebro-spinal fluid of five cases of sleeping sickness in Uganda, and the importance of this discovery is best shown by Sir David Bruce's acknowledgment in the fourth volume of the Sleeping Sickness Commission.

This *most interesting discovery* of Dr. Castellani's, which was due to his introduction of the method of centrifuging the cerebro-spinal fluid in his search for streptococci, has been of the utmost value to the present Commission. It put them at once on the right track, and led to the easy and rapid elucidation of the hitherto mysterious disease. Without knowledge of his observation they might have worked for months in the dark, and, in truth, they might even have returned to England still ignorant as to the true cause of the disease.

Castellani had already given it as his opinion that a streptococcus was the cause of the disease, he believing that the trypanosome, like the filaria perstans, was an accidental concomitant. If he had been able to extend his observations he might have changed his opinions. I mention this because a letter appeared in the *Times* disputing Professor Ehrlich's right to give any credit to Castellani for the discovery of the cause of the disease.

A large number of specimens of brains of cases of sleeping sickness were sent to me to examine by the Commission, and I could add little or nothing to my original description of the histological changes found in two cases of Manson

which were in Charing Cross Hospital. I never succeeded in finding the trypanosomes in sections, but I have seen them in brain smears; the trypanosomes were always found in the cerebro-spinal fluid by Sir David Bruce.

Now the trypanosome of sleeping sickness is, comparatively to the spirochæte pallidum, a large organism, and therefore it is not surprising that no one before Noguchi was able to find the specific organism of syphilis in the brains of general paralytics; although to my mind the facts which had already accumulated since Fournier pronounced this disease to be parasyphilitic seemed to be overwhelming proof that if there were no syphilis there would be no general paralysis.

CLINICAL AND ETIOLOGICAL FACTS SUPPORTING THE SYPHILITIC ORIGIN OF GENERAL PARALYSIS AND TABES DORSALIS.

1. A history of syphilitic affection, usually of a mild form as regards secondary and tertiary symptoms, can be obtained in as large a proportion of cases of general paralysis as in obvious syphilitic skin lesions. 2. A correlation of the incidence of syphilis and the incidence of general paralysis in the two sexes according to the social grade. 3. In 60 cases of the juvenile form of general paralysis I found evidence of congenital syphilis either in the family history or signs on the body of the patient in nearly every instance, and in not one could it be excluded. In the juvenile form the sexes are equally affected. Mental stress, alcoholism, and sexual excesses, the previously attributed causes, can be excluded. 4. I showed that Fournier was right in asserting that tabes and general paralysis pathogenetically were one and the same disease, affecting different parts of the nervous system, for I collected 70 cases of tabo-paralysis, and I found that some began as tabes and ended in general paralysis; in others the spinal and cerebral symptoms started simultaneously; while again in others it began with optic tabes and ended in spinal tabes or tabo-paralysis. About 10 per cent. of cases of tabes end in tabo-paralysis. 5. The most convincing proof of the syphilitic nature of general paralysis was Krafft-Ebing's inoculation of nine paralytics with no history and no signs on the body, none of whom were capable of re-infection. In all my very large experience I have never seen a primary sore or secondary eruption on a paralytic.

This chain of circumstantial evidence was strong enough for most neurologists, and eminent authorities such as Sir David Ferrier, Dr. Drummond, and many others were convinced, as I was, that if there were no syphilis there would be no tabes or general paralysis.

THE SEARCH FOR THE SPECIFIC ORGANISM IN THE BRAIN.

Then came the discovery of the spirochæta pallida of syphilis by Schaudinn, and the successful inoculation of anthropoid apes by Metchnikoff, Hoffmann, Neisser, and others, which was extended to other animals such as apes and rabbits. This was followed by the introduction of the Wassermann reaction, and the blood of persons who were reacting to the syphilitic organism was shown to have complement fixation. It was soon found that general paralytics invariably gave the reaction in the most marked manner, and later Plaut showed that the cerebro-spinal fluid gave a positive reaction in 96 out of 97 cases, the serum giving it in every case. Indeed, the cerebro-spinal fluid was much more certain to give a positive reaction than syphilis of the nervous system. My assistant, Dr. J. P. Candler, has found 98 per cent. of paralytics give a certain positive reaction of the fluid, and the results have been already confirmed in over 200 cases by post-mortem examinations.

The introduction of the ultramicroscope led us to look for the spirochæte in the cerebro-spinal fluid in a number of cases, but we did not meet with success. I also made a great number of preparations of sections of the brain by the Levaditi method, but, like Minea and Marinesco, who examined 30 cases of general paralysis, I was unsuccessful in finding the spirochæte. I therefore concluded that in all probability there was a latent granular form, and in the fourth volume of the System of Syphilis—"Syphilis of the Nervous System"—I put forward this view, supporting it by the fact that I had seen in smear preparations enormous numbers of chromidian granules; likewise in sections of syphilitic papules, where only a few spirochætes were seen, I have observed these granules. But my main argument was based upon the important observation by Leishman that the spirillum of tick fever exists in a granule form in the cells of the body of the tick, and he could cause these granules to develop into spirillary forms. Again, Neisser was able to infect monkeys with the marrow of bone of infected animals, although the most diligent search showed no spirochætes. Noguchi himself thinks there may be a granule form; in fact, his culture experiments seem to indicate such. Moreover, Balfour and O'Farrell have stated that they have observed a shedding of granules after acting upon spirochætes with salvarsan. The paper published in February by Noguchi and Moore, in which it was shown that Levaditi-silver-stained-preparations of 70 cases of general paralysis showed spirochætes in 12 of them, was an epoch-making discovery.

When I was at the Rockefeller Institute in April, Noguchi was good enough to give me one of these preparations, which left no doubt in my mind of their existence. Since this discovery by Noguchi we have a new conception of the disease on the sure ground of direct observation, yet there are still many facts unexplained; nevertheless, all the evidence points to the fact that the term "parasyphilis," meaning a post-syphilitic affection, must be superseded by the term *parenchymatous syphilis*. Noguchi has examined another 130 cases of general paralysis, and in this second series he found the spirochætes in 36, making in all 48 out of 200. In 6 cases he examined fresh brains by means of the ultramicroscope, and in one of these he found spirochætes. In 12 cases of tabes he found the organism in one only. Marinesco and Minea have reported that 1 case out of 26 yielded a positive result by the silver method. This case showed nests of spirochætes, as many as 60 in one field of the oil immersion being counted. I throw on the screen a photomicrograph of a specimen sent me by Professor Marinesco. (Fig. 5.)

Marie, Levaditi, and Bauchowski have reported 3 positive results out of 30 cases of general paralysis by the silver method. In a more recent publication they claim to have shown that spirochætes are constantly present in the brains of general paralytics dying in seizures. They emphasise the importance of a systematic examination of all the convolutions of the cortex until a positive result is obtained. They do this by sections, by films prepared from an emulsion of the cortex and

subsequent examination by the Indian ink method or the silver method of Fontana. They found spirochætes in all the 7 cases examined. They observe that if one can localise the muscular epileptiform seizures a guide will be obtained of a focus of spirochætes in the neighbourhood of the portion of motor area affected. I show a preparation kindly sent me by M. Marie. (Fig. 4.) Forster and Tomasezewski obtained 2 positive results out of 4 cases in which the material was taken from the patient by the Neisser-Pollak puncture method and examined by the ultramicroscope.

Noguchi's Experimental Observations.

Before referring to my own observations I will give a *résumé* of Noguchi's experiments relating to the transmission of the spirochæte pallidum obtained from the brains of general paralytics to the rabbit, and the experimental production of syphilitic encephalitis in this animal.

Noguchi inoculated into the testicles 36 rabbits with the emulsion of six different specimens of brains of general paralytics in the fresh state. At the end of 97 days in one case and 102 days in the other a small but typical induration of the testicle and scrotal skin occurred. In the first case the spirochætes were few, in the second they were abundant. It is interesting to note how slow was the development as compared with the transmission by infection made with material obtained from a chancre or secondary lesion; in the latter case the lesions generally appear after an interval of four to six weeks, rarely two months elapse.

The Existence of the Parasites in the Parenchyma of the Nervous System in Relation to their Resistance to the Action of Drugs.

This interesting observation of Noguchi may be correlated with the many facts which seem to point to the specific organism that produces general paralysis being either a form which has been modified by the widespread use of mercury or modified by passing through the bodies of individuals who have acquired resistance. A number of instances of infection have been reported which seem to point to the possibility of a specific organism; the most convincing being that of Brosius in which seven glass-blowers were infected, four of whom ten years later suffered with tabes or general paralysis. Certain it is that the average time after infection in general paralysis and tabes is 10 years, and the signs and symptoms of the disease externally manifest in the form of skin and bone lesions are as a rule either absent, mild, or obscure; whereas in syphilitic brain and cord disease the great majority of the cases occur within the first four years after infection, the greatest percentage occurring in the first and second years. Whereas the signs and symptoms of the latter are coarse and obvious and with generally well-marked skin eruptions amenable to treatment, the former—the so-called parasyphilitic, or, as I shall prefer to call them, parenchymatous syphilitic disease—are late (quaternary) and comparatively unamenable to treatment. Is this because they are mercury-fast organisms, or is it because they exist in a latent granular or intracellular form in the parenchyma of the nervous system, where they cannot be attacked by the drugs such as arsenic, mercury, and antimony? By analogy this does not seem improbable, seeing that in sleeping sickness when once the trypanosome has invaded the nervous system, atoxyl and other arsenical and antimonial preparations which were intravenously injected fail to kill the parasite and arrest the progress of the disease. Moreover, there is other evidence in favour of this conclusion. Arsenic is not found in the brain when large quantities of arsenic have been taken in cases of poisoning; it has not been found in the fluid after injection of salvarsan intravenously. The late Professor Goldmann has shown that the choroid plexus intercepts dyes which have been injected intravenously in large quantities, 100 c.c. of a 1 per cent. solution of trypan blue, whereas 1–2 c.c. of 0·5 per cent. solution injected by lumbar puncture stains the whole cerebro-spinal axis except the cortex, penetrating and staining all the neurones. This, as I shall tell you later, has led to the idea of a new method of treatment, not by injecting weak doses of salvarsan or neosalvarsan intrathecally, for this would be a most dangerous proceeding; to kill the parasites you might kill the neurones and the patient.

The only case of trypanosomiasis ugandensis that I have heard of as having recovered was a Sikh whose brain was sent to me for examination. He lived five years after infection and was treated for a long time—18 months—with atoxyl, then with mercury, for he became intolerant of arsenic and had contracted syphilis. Three years after infection his fluid was examined by Sir David Bruce and found free of trypanosomes and he showed no signs or symptoms of sleeping sickness; he died two years later. I examined his brain and found no signs of perivascularitis or neuroglia proliferation—histological changes which were present in every case, 30 in all, that I had previously examined and which during life had exhibited the characteristic lethargy.

These facts show that the presence of the trypanosome in the central nervous system is necessary to produce the meningo-encephalitis characteristic of the disease, although to my mind it is possible that toxins may pass into the central nervous system along perivascular and perineural lymphatics, as Orr and Rows have shown experimentally.

Further Experiments of Noguchi.

Noguchi has shown that the central nervous system of monkeys and rabbits is very resistant to syphilitic infection, even when the virus is introduced directly into the cerebral substance. Most animals remain in perfect health during an indefinite period after the intracerebral inoculation of spirochæte pallidum. Noguchi conceived the idea that it was necessary to sensitise these animals by repeated intravenous injections with dead and living spirochætes; this he did for five months. At the end of this time he made an intracerebral inoculation or subdural insertion of an emulsion of minute particles of testicular syphiloma of the rabbit, rich in spirochætes. Twelve sensitised and 4 normal rabbits were employed, all of which remained healthy for two months; then some of the sensitised rabbits showed symptoms. The animals were killed and 3 of those which had been sensitised showed cerebral changes not unlike those of a syphilitic meningo-encephalitis. For my own part, I am doubtful whether these experiments prove very much one way or the other as regards the production of general paralysis in animals.

Personal Observations.

I will now refer to the recent work concerning the existence of the spirochæte in the brains of cases of general paralysis which has been done

under my direction at Claybury; also I will endeavour to demonstrate the difference in the pathogenesis and histology of syphilitic meningo-encephalitis and general paralysis and syphilitic meningo-myelitis and tabes dorsalis. I will also compare the histology of sleeping sickness, a trypanosome infection, with the syphilitic spirochæte infections, and the deductions which can be made therefrom. Lastly, I will call your attention to an inquiry into the incidence of general paralysis in the different parishes and districts of the county of London.

SPIROCHÆTES IN THE BRAINS OF GENERAL PARALYTICS.

Having failed to find the specific organism in sections stained by the Levaditi method after a diligent search of numbers of sections from numbers of cases—in this search I was aided by my assistant Mr. Charles Geary, Dr. Fisher, and Major Fink—I resolved to adopt the Indian-ink method (Burri); and by this method I soon obtained apparently positive results. I say apparently, for it must be admitted that delicate curled filaments may be mistaken for spirochætes, and unless these spiral forms have been observed in the living state moving on the dark-ground microscope convincing proof of the presence of spirochætes would be wanting. Yet I feel convinced they were in the light of further researches by the Fontana method and the ultra microscope.

I have thought that active pullulation of the specific organisms might be associated with epileptiform seizures, and in support of this I may observe that I have found that unilateral convulsions of a severe nature were at the necropsy associated with a great wasting of the corresponding hemisphere. For example, I have found after prolonged right-sided seizures a marked speech affection and a hemiparesis; at the post-mortem examination the left hemisphere has in some instances of this kind weighed as much as 100 grm. less than the right. In the light of recent researches of Noguchi it is probable that the active development of the spirochætes leads to the production of toxins which cause a rapid destruction of the neurones in two ways—firstly, by the direct destructive effects of the toxins on the neurones; and secondly, by irritation and proliferation of the cell elements of the perivascular lymphatic sheaths, the capillary endothelium, and the neuroglia cells, the perivascularitis and capillary changes causing blood stasis and destructive effects on the neurones secondary to these inflammatory changes

But to return to the demonstration of spirochætal foci in the brains of paralytics. Having this hypothesis of association of active proliferation of the specific organism and the onset of seizures I wrote an encyclical letter to the superintendents of all the ten asylums asking them to forward me the brains of patients who just prior to death had had seizures, and from these brains, which numbered in all 11, I obtained by the Indian-ink method spiral forms in 8 cases. Of 7 cases dying at Claybury in the ordinary routine and not selected, in 3 spiral forms were found (*vide* illustration). Portions of all these 18 brains were fixed and stained by Noguchi's modified silver method and sections made; so far specimens from eight brains have been examined but without results; indeed, the fibrils in many of the specimens are stained as well as in Levaditi preparations.

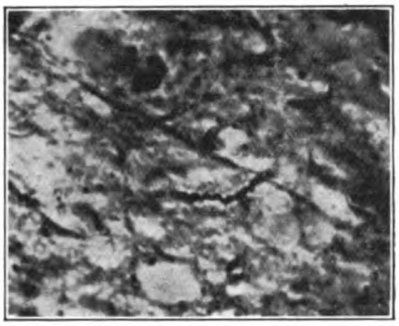
My assistant, Mr. Geary, has now succeeded in staining films with the Fontana Tribondeau silver method, and we have obtained excellent results in 3 cases; in one of these—a brain sent from Horton, which was comparatively an early case—numbers of spirochætes were found in film preparations (*vide* illustration) of the second frontal convolution, but from no other of many regions examined. This shows the truth of Marie, Levaditi, and Bauchowski's observation that all the convolutions of the cortex require to be examined systematically. The spirochætes of this case four days after death were also observed moving, it is true only sluggishly, by means of the ultra-microscope. Spirochætes were not found in films from the second frontal when the brain was received; but 24 hours later, when the substance was soft and a certain amount of decomposition had occurred owing to invasion of other organisms, they were found in abundance in this one region.

Seeing that fœtal tissues containing a great abundance of spirochætes are generally decomposed and contain numbers of other organisms, as also chancres and the enlarged lymphatic glands, it is possible that the secondary microbial invasion by aerobic organisms may possibly favour in some way the development of the non-aerobic specific organisms, as we know is the case in tetanus. Certainly my experience teaches that pneumonia, dysentery, septicæmia, and other intercurrent secondary microbial infections are especially liable to be associated with seizures, not necessarily generalised, but often unilateral in character.

Further experiments and observations which I am now making will, I hope, help to decide whether the hypothesis of a latent granule form, which under favouring circumstances develops into a spirochætal form with production of toxins, is true or not. The great difficulty is that the search for spirochætes in the brain is like looking for the proverbial needle in a haystack; not finding does not mean non-existence. The investigation is attended with great technical difficulties, and there is still much to be done before we can fully understand the pathogenesis and pathology of these late syphilitic diseases of the nervous system.

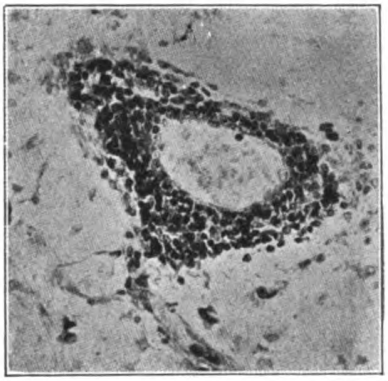
INTRATHECAL INJECTION OF PATIENTS' SERUM AFTER SALVARSAN TREATMENT.

In respect to the early acute infection of the central nervous system, I may mention that I recently had under my care a case of gummatous meningo-encephalitis. Infection occurred in February last, and in spite of intramuscular injections of salvarsan and mercury severe cerebro-spinal symptoms set in in September. The cerebro-spinal fluid showed a great abundance of lymphocytes, and a spiral form which resembled a short spirochæte was found in one of the Indian-ink preparations of the centrifuged deposit. As I could not find spirochætes moving with the dark-ground illumination this is not claimed as convincing proof. The cerebro-spinal fluid, like the blood, in this case yielded a very marked complement fixation. He subsequently received an intravenous injection of 0·4 grm. neosalvarsan with great improvement, but the greatest improvement resulted from an intrathecal injection of serum taken one hour after another dose of neosalvarsan had been administered; subsequent to this the fluid became less positive and the lymphocytosis disappeared.



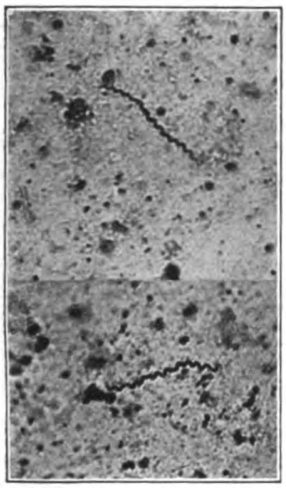
The serum was tested for arsenic and yielded no result; the legitimate conclusion being that the action of the serum is due to the presence of antibodies in

FIG. 1.



Spirochæte in smear of condyloma stained by Giemsa. (× 1800.)

FIG. 4.



Section of brain stained by a silver method from a preparation by Professor A. Marie. (× 1740.) Many spirochætes are seen in the field but only one is in focus.

the blood and not to the arsenic. But seeing that I have found that intraveous injections and even intramuscular injections of salvarsan may convert a positive Wassermann reaction of the fluid in general paralysis into a negative reaction, and thus account for the improvement, it is necessary that the serum of another individual who had received an intravenous injection of salvarsan should be injected into the lumbar subarachnoid sac before it could be claimed that the antibodies in the serum were the cause of the improvement. Dr. Swift, of the Rockefeller Institute, who claims to have obtained very hopeful results by this method of treatment in tabes dorsalis, said at the International Medical Congress that he had done this with equally satisfactory results. If this be true it would appear that mercury and arsenic are spirillocidal either by causing the development of antibodies or by furthering their spirillocidal action. Dr. George Robertson, of Morningside Asylum, from his experience, does not claim to have attained a cure, and is quite judicial in his statement regarding the effect of this treatment in general paralysis, for he says:—

> Although success has not been obtained there are hopeful indications, for it appears that the disease process, if not suppressed, is at least touched in half the cases. The decrease in the lymphocytosis, the diminution in the intensity of the Wassermann reaction, and its disappearance for over a year in some cases are hopeful signs of the most convincing character.

Dr. Fisher, of the Rockwood Hospital, Kingston, Canada, who for some months past has been working under my direction at the Pathological Laboratory, Claybury, had the idea of treating general paralysis by this method, and in the spring of 1912, by the kindness of the superintendent, Dr. Ryan, Dr. Fisher took 7 cases of advanced general paralysis and rendered the blood negative to the Wassermann reaction by repeated intravenous injections of salvarsan. Then under rigid antiseptic precautions he withdrew 15 to 20 c.c. of blood from the median basilic vein of the patient's arm, placed this in a cool chamber for one hour, separated the clot, and centrifuged the serum for half an hour in sterile tubes. Next he performed lumbar puncture and withdrew cerebro-spinal fluid of an amount equal to that of the serum to be injected, which is slowly introduced, being kept at the body temperature. The patient is allowed for one hour to lie flat on his back without a pillow and with the foot of the bed raised. This treatment was repeated every week for the first three months, then every two weeks for the next four months. No untoward symptoms occurred in any of the cases under treatment, and he has learned that the cases have greatly improved, and apparently there has been an arrest of the symptoms so far.

In the Oliver-Sharpey lectures which I delivered at the Royal College of Physicians of London in April, 1910, I gave many reasons from experiment and observation why it seemed probable that the cerebro-spinal fluid functions as the lymph of the brain. I also pointed out that, inasmuch as normally it contains no proteids or cell elements, if microbial invasion occurred it tended to spread rapidly because the fluid normally contained no bactericidal action nor leucocytes capable of combating microbes. These experiments of introducing serum of patients, which presumably contains antibodies, rest therefore upon a scientific basis if my conclusions are correct. At the same time it is difficult for the serum to arrive at the crannies in the cortex by injecting it by lumbar puncture into the subarachnoid space, for Goldmann's researches with trypan blue show that the cortex is unstained when the dye is introduced by lumbar puncture. He found, however, that the cortex is well stained when the dye is introduced by trephining the calvaria. It is possible that by repeated injections, as in Dr. Fisher's experiments, the antibodies may reach the cortex by lumbar puncture. Goldmann's work, however, shows the desirability of trying the method of introducing the serum directly into the subdural or subarachnoid space of the cortex. Unfortunately, I have not the authority to try this in my capacity of pathologist to the London County Asylums.

THE WASSERMANN REACTION.

I have already mentioned that in practically every case of general paralysis a positive Wassermann reaction is obtainable in the cerebro-spinal fluid, whereas not more than 50 per cent. of the cases of tabes yield a positive reaction. Why is this? In my opinion the reaction in the cerebro-spinal fluid is evidence of the existence of the parasites or their toxins in the central nervous system. I consider that it is the toxins produced by the active generation of the parasites which cause the reaction, the degeneration of the neurones, and the active proliferation of the lymphocytes, plasma cells, and neuroglia cells. For several reasons I consider it is a reaction of the neurones which gives rise to the euglobulin in the fluid that serves as a complement fixative. Firstly, because the toxins of other specific organisms, for example, tubercle, give rise to lymphocyte, plasma cell, and neuroglia proliferation without producing complement fixative in the fluid. Secondly, because some cases—in fact, the majority of cases of cerebro-spinal syphilis, even cases with active meningitis and enormous numbers of lymphocytes in the fluid—nevertheless give a negative Wassermann reaction, and there is no complete parallelism between lymphocytosis and degree of complement fixation. The experiments of Levaditi and Yamanouchi, however, show that it is the toxin of the spirochætes, and not the parasites themselves, which induces the typical lymphocyte and plasma cell reaction. Thus they introduced a small portion of infected cornea of a rabbit containing abundant spirochætes into the anterior chamber of the eye of a healthy rabbit, and they observed a characteristic cell reaction in the cornea of the normal rabbit before there was an invasion by spirochætes. This experiment shows that a localised nest of spirochætes in the cerebro-spinal axis or even outside the central nervous system, provided the toxins can be conveyed by lymphatics, can set up the characteristic cell reaction in the perivascular spaces of the nervous system, each fresh dose of toxin leading to a remission of symptoms and decay of nervous structures.

We know that normally the choroid plexus does not let this toxin pass into the cerebro-spinal fluid any more than it does the antibodies, for the blood may give a very strong reaction in cases of syphilis, and yet the cerebro-spinal fluid not show the slightest trace of reaction. Now the cerebro-spinal fluid in great part is secreted by the choroid plexus into the lateral ventricles; consequently fluid withdrawn from the lateral ventricles should give a less marked reaction than that withdrawn by lumbar puncture, for the latter would have been in contact longer with the nervous tissue. Acting

upon this hypothesis I asked my assistants, Dr. Candler and Mr. Mann, to examine a number of cases to test its validity. In 38 cases the fluid was withdrawn as soon after death as possible from the lateral ventricles and by lumbar puncture; the result obtained in all the instances was to show that the fluid obtained by lumbar puncture was from two to ten times as strong in linking up complement as that from the ventricles. Doubtless, if the fluid could be obtained as it was secreted during life into the lateral ventricles no specific globulin would exist in it.

Tabes being a much slower decay of the neurones, and limited to the posterior spinal afferent neurones in the great majority of cases, presumably is occasioned by small doses of toxin finding entrance to the posterior columns by limited and defined channels; indeed, it is conceivable that the syphilitic toxin may arise in lesions of the thoracic or abdominal aorta which, passing along the lymphatics of vessels, gains access to the lymphatics of the spinal cord, the circulation of the lymph being along the course of the afferent roots. This seems probable from the experiments of Orr and Rows, who have, by tying celloidin capsules containing microbial toxins on the sciatic nerve, produced a perivascularitis in the posterior columns with degeneration of exogenous afferent systems like those of tabes. Possibly the perivascular lymphatics of the carotids may convey toxins or even the specific organisms to the fronto-central region of the brain in cases of general paralysis. This is a not improbable source of infection, for if skin lesions of syphilis are rare in this disease, syphilitic nodular fibrosis of the aorta is extremely common.

LESIONS IN EARLY AND LATE STAGES.

A comparison of the lesions of syphilitic disease of the brain and cord in early stages after infection with those occurring late, on an average 10 years after infection, shows that in both there is the same perivascular infiltration with lymphocytes and plasma cells; this is the reaction to the toxin produced by the parasite. In syphilitic brain disease there is also an endarteritis, sometimes localised, sometimes universal, and it is the blocking of the vessels by this inflammatory condition, especially when associated with thrombotic occlusion, which occasions the symptoms of so varied and obtrusive a character and sudden in onset. So also in focal meningomyelitis the localised decay of neuronic structure giving rise to paraplegia is due to obliterative endarteritis more than to the meningeal and peri-vascular inflammatory changes. If the vessels are not damaged extensively remarkable curative results by specific treatment are obtainable. The Argyll-Robertson pupil so characteristic of tabes and general paralysis is not seen.

In general paralysis examination of the vessels of the brain seldom shows any evidence of endarteritis; if there is any extensive vascular inflammation it is in the capillaries, where undoubtedly the endothelium undergoes active proliferation and budding; the reason for this cannot be the toxin circulating in the blood, otherwise the endothelium of the arteries and veins would show it. Probably the specific toxin is in all the interstices of the nervous tissue wherever the cerebrospinal fluid irrigates; thus it comes in contact with the capillary endothelium and excites its active proliferation, with capillary blood stasis, a histological condition that is especially characteristic of general paralysis.

I have met with a few cases of syphilitic brain disease which have terminated in typical general paralysis, and Straussler has reported several. A striking feature of general paralysis and the most consistent naked-eye phenomenon, which is not seen to anything like the same degree in syphilitic brain disease nor in sleeping sickness, is the granular condition of the ventricles, especially the fourth ventricle. This indicates the prolonged existence of an irritant toxin in the cerebrospinal fluid. The greater the wasting of the brain the more pronounced is this change. The wasting of the fronto-central convolutions and of the whole cerebral cortex, but to a less degree, is a characteristic feature of this disease (general paralysis) as compared with syphilitic brain disease. Doubtless this is in part due to the vascular changes, but inasmuch as in sleeping sickness the perivascularitis and meningitis may be as extensive as, and even more universal and extensive than in general paralysis, it must be concluded that there is also in this disease a primary and progressive decay of the neurones, owing to the continuous action of the toxin sensitising the nerve cells and causing them to react to such a degree that the normal metabolic equilibrium is destroyed and degeneration ensues, so that we have, as Noguchi asserts, a parenchymatous encephalitis.

THE INCIDENCE OF GENERAL PARALYSIS IN THE POPULATION OF LONDON.

If it could be assumed that 2–3 per cent. of persons who acquired syphilis developed general paralysis it might help us to estimate approximately the extent of syphilis in a population; for inasmuch as general paralysis is a disease fatal within a few years of admission to the asylum accumulation of cases suffering from this disease does not occur, consequently the death-rate per annum is about equal to the admission rate. I will throw on the screen a lantern slide showing the incidence of general paralysis in the general admissions to the London County Asylums during the years 1911–1912 from the parishes north and south of the Thames, east and west; I will point out the main results which these tabulated statistics show.

North of the Thames—West-end parishes. Total population equals 1,376,083. Male admissions 1183; of these 205 were general paralytics, so that the percentage of paralytic male admissions is 17·3. Female admissions 1236; of these 31 were general paralytics, so that the percentage of paralytic females is 2·5. So that general paralysis is seven times as frequent in males as compared with females in West-end parishes north of the Thames.

North of the Thames—East-end parishes. Total population equals 1.282,911. Male admissions 930; of these 123 were paralytics. so that the percentage of paralytic male admissions is 13·2, against 17·3 in the West-end parishes north of the Thames. Female admissions 981; of these 34 were general paralytics, so that the percentage is 3·4 in eastern parishes north of the Thames, against 2·5 per cent. in the West-end.

In West-end parishes north of the Thames we will find that 1·75 per 1000 residents were admitted in the two years, and of these 9·7 per cent. were general paralytics. In East-end parishes north of the Thames 1·49 per 1000 were admitted in the two years, and of these 8·2 per cent. were general paralytics.

In West-end parishes south of the Thames the results obtained are somewhat different, for both males and females have a higher percentage of general paralytics in the western parishes;

however, this quite accords with the character of the population in Wandsworth and Lambeth.

In the western parishes the total population is 777,321. The male admissions are 537; of these, 97 are paralytics, a percentage of 18·3. The female admissions are 641; of these, 20 are general paralytics, percentage 3·1. Both male and female incidence of paralysis are high.

In the eastern parishes the total population is 1,066,989. The male admissions are 741; of these, 102 are paralytics, a percentage of 13·7. The female admissions are 825; of these, 23 are paralytics, a percentage of 2·7.

The western parishes are higher in both male and female paralytics; in the former 10 per cent of the total admissions are paralytics, to 7·9 per cent. in the latter.

These facts entirely agree with what we know of the incidence of general paralysis in the two sexes from practice—viz., the lower we go in the social scale the more common becomes this disease in the female sex; whereas general paralysis is common to all grades of society in the male sex, it is very rare in the better and respectable classes of females in all grades of society. Probably these statistics give a rough idea of the relative prevalence of syphilis in the two sexes.

We may conclude, therefore, that syphilis is commoner in the West-end among males and in the poor East-end among females. Seeing that a very considerable number of paralytics in the West-end do not come into the county asylums it may be assumed that the ratio of six males to one female is well under the mark.

PLAGUE RATS AT SEATTLE.—Seattle, the largest port on Puget Sound, the northernmost of the large ports on the Pacific seaboard of the United States, has found plague rats and is now anxious about possible danger. At this point it becomes at once clear what a strength their public health service is to the United States. Instead of anxiously advertising for casual doctors to assist them, they get an additional officer of the service detailed from San Francisco for duty at Seattle, and have many others, experts at this particular work, to help them if required. No plague rats have been so far observed in the neighbouring British Columbian ports, Victoria (60 miles away), and Vancouver (100 miles north), but the Seattle papers are tartly suggesting that that is perhaps only because they have not been looked for, and that the quarantine suggested against ships from Seattle is unnecessary.

GONORRHŒA PHYLACOGEN:

REPORT ON AN INVESTIGATION INTO ITS VALUE IN THE TREATMENT OF SOME GONOCOCCAL INFECTIONS.

BY L. W. HARRISON, M.B. GLASG.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

FOR the opportunity of making this investigation I am indebted to the Editor of THE LANCET, who suggested it and provided me with a supply of the remedy.

Phylacogen is the trade name applied to a series of solutions of bacterial products prepared according to the directions of Dr. A. F. Schafer (California), their inventor. Dr. Schafer's theory is that every bacterial disease is due to mixed infection. The micro-organism to which the disease is usually attributed may preponderate, but others which are commonly found in the body play some part in producing the symptoms which the patient displays. Accordingly, the attack must be directed not only against the specific germ but also against a host of others which assist or are assisted by it. According to a handbook issued by the firm responsible for its manufacture, a basic phylacogen is prepared by mixing together filtrates (through porcelain) of cultures of "staphylococcus pyogenes (albus, aureus, and citreus), streptococcus pyogenes, bacillus pyocyaneus, diplococcus pneumoniæ, bacillus typhosus, bacillus coli communis, bacillus diphtheriæ, streptococcus rheumaticus, and streptococcus erysipelatis." This mixture constitutes "mixed infection phylacogen" and enters into the constitution of each of the specific phylacogens (erysipelas, gonorrhœa, pneumonia, and rheumatism). Each of these is prepared by mixing together equal parts of "mixed infection phylacogen" and the filtrate of a pure culture of the specific micro-organism. It will be realised, therefore, that phylacogens are not exactly vaccines in the commonly accepted sense of the word, since they contain no solid bacteria. They are more analogous to the toxins which are used for the manufacture of antitoxins. It is not intended here to discuss Dr. Schafer's theory, but to relate the results of a short experience of gonorrhœa phylacogen and to offer some comments on the progress of the patients who were treated with this remedy as contrasted with that of similar cases treated by ordinary methods. It is necessary first, however, to make a few remarks on the administration of gonorrhœa phylacogen and on its side-effects.

Methods of Administration and Dosage.

According to the recommendations issued by the makers, gonorrhœa phylacogen may be administered subcutaneously or intravenously, the former for choice, and always for the initial dose. The intramuscular method is not recommended, but the reason for this is not stated, nor is it quite clear, unless it is for reasons of safety. In the series of cases related below I employed the intramuscular as well as the subcutaneous and intravenous methods and found that, while the therapeutic effect of the subcutaneous injection was in no way superior to the intramuscular, the local reaction which followed the intramuscular injection was more bearable than that which followed the subcutaneous, especially when large doses were employed.

With regard to dosage, for subcutaneous injection the original recommendation was to commence

with 3–5 c.c. and increase to 10, 15, or even 20 c.c., but in a later pamphlet the makers now recommend smaller doses than this—1 or 2 c.c. at first, increasing each dose by 1 or 2 c.c. till a maximum of 10 c.c. is reached. For intravenous injection it is now recommended to commence with 0·125 c.c. to 0·25 c.c., increase very gradually till a dose of 1 c.c. is reached, and thereafter by increments of 1 c.c. to a maximum of 5 c.c., avoiding if possible any marked constitutional reaction. The interval which is recommended between doses is 24 hours or less unless a marked reaction follows the injection, when it may be prolonged to a maximum of 48 hours. A longer interval is deprecated on account of the likelihood of relapse, and for the same reason it is urged that the injections be prolonged till at least 10 days after the patient is relieved of his symptoms.

I have endeavoured to follow these directions as closely as circumstances would allow, but for obvious reasons have not felt justified in prolonging the treatment in cases where it was clear that the remedy was having no effect on the disease. As will be mentioned, the reaction after an injection of gonorrhœa phylacogen is often distinctly unpleasant, and it is not justifiable to repeat this indefinitely when there appears to be no hope of compensatory benefit.

Reaction following Injections of Gonorrhœa Phylacogen.

After subcutaneous, and to a less extent after intramuscular, injection, the site of the injection becomes distinctly painful, the discomfort depending largely on the size of the dose and to a certain extent on the patient. Frequently it lasts well into the following day and may deprive the patient of his sleep. The general symptoms depend on the size of the dose, the patient, and the method of administration. As a general rule, intravenous injections are followed by more constitutional disturbance than intramuscular or subcutaneous. Within an hour or two of the injection there is generally a feeling of chill, and, especially after the first few intravenous injections, this may increase to a definite rigor. The temperature rises to a variable height by the same evening. Generally it reaches 100° to 101° F., but in some of my cases it rose to 104°, and in one case an intramuscular injection of 10 c.c. was followed by a temperature of 105·6°. Most of my patients who received intravenous injections suffered from headache, which was often so severe as to make them prefer the pain following an intramuscular or subcutaneous injection. The majority of patients seem to develop some tolerance to the remedy, the reaction following later not being so severe as after the initial doses.

I have treated with gonorrhœa phylacogen 16 cases, including 1 case of gonococcal arthritis and 10 of epididymitis, and the history of each of these is briefly related below. In cases where it was not contra-indicated patients suffering from urethritis received appropriate local treatment in addition. To avoid unnecessary repetition, by "phylacogen" is meant "gonorrhœa phylacogen" in the following case reports.

CASE 1.—Gonococcal arthritis two days, with very severe pain in the left hip, both knees and both ankles. Moderate swelling of visible joints. Purulent urethral discharge containing fairly numerous gonococci. Intramuscular injection of phylacogen 3 c.c. was followed on the next day by considerable relief of pain in all joints. During the succeeding four days intravenous injections of 1 c.c., 2 c.c., 3 c.c., and 4 c.c. Stiffness and pain completely disappeared and the joints became less swollen; urethral discharge containing gonococci in fair numbers persisted. Five days later return of pain and swelling in the right ankle. Seven intravenous injections of 3 c.c. phylacogen on successive days, during which pain disappeared from ankle, but the right wrist became affected on the second day and the left knee on the seventh day. Intramuscular injection of 10 c.c. phylacogen was followed by relief of all pain. Subsequent progress towards recovery was uneventful.

The history of this case, unfortunately the only one of gonococcal arthritis which I have had an opportunity of treating with phylacogen, appears to support those published by others in testifying to the good effect of phylacogen on gonococcal arthritis.

CASE 2.—Gonorrhœa 8 weeks; epididymitis 1 week. Testicle considerably swollen and rather tender, but no marked pain. Intramuscular injection of 3 c.c. phylacogen. Testicle on following day more painful. Seven intravenous injections of phylacogen during the following 13 days in doses rising from 1 c.c. by increments of 1 c.c. to a maximum of 3 c.c., the injections being generally on alternate days on account of the severity of the reactions. Swelling gradually abated but returned with slight pain on the day after the last of these injections. Intramuscular injection of 10 c.c. phylacogen was followed by relief of all pain. The patient was discharged from hospital a week later for special reasons, the testicle being then about twice the normal size but free from discomfort.

CASE 3.—Gonorrhœa 2 years, with frequent relapses of acute urethritis. Epididymitis 3 days, with severe pain and swelling. Intramuscular injections of 10 c.c., 15 c.c., and 20 c.c. phylacogen during first four days; the testicle became slightly smaller and more comfortable. Intramuscular injection of 20 c.c. phylacogen two days later and six subcutaneous injections of 5 c.c. phylacogen on successive days. Progress much the same as in similar cases treated without vaccine. Urethral discharge continued, with fairly numerous gonococci.

CASE 4.—Gonorrhœa 21 days; epididymitis one day. Five subcutaneous injections of phylacogen in doses increasing from 1 c.c. to 4 c.c. on alternate days. Local and general reaction after each injection fairly severe. Progress apparently uninfluenced by phylacogen.

CASE 5.—Epididymitis one day, with considerable pain and swelling. Intramuscular injection of 5 c.c. phylacogen followed by four intravenous injections on successive days and in doses increasing from 1 c.c. to 3 c.c. Each injection followed by severe reaction. No improvement. Two days later intramuscular injection of 15 c.c. phylacogen was followed by considerable relief of pain. Dose repeated two days later, but two days after this severe relapse of pain and swelling. Phylacogen discontinued and polyvalent stock vaccine commenced in weekly doses. This was followed by steady improvement and there was no further relapse. In this case a large dose of phylacogen seems to have relieved pain, but steady administration of the remedy failed to prevent a severe relapse.

CASE 6.—Gonorrhœa 21 days; epididymitis 4 days. Epididymis moderately swollen, rather tender, but not very painful. Three intramuscular injections of 10 c.c. phylacogen on alternate days, each injection being followed by severe reaction. Testicle on the fifth day not so tender. From the seventh to the thirteenth day of phylacogen treatment six subcutaneous injections of phylacogen, commencing with 1 c.c. and increasing by 1 c.c. to a maximum of 5 c.c. Relapse of pain and swelling on the thirteenth day. Subcutaneous injections continued on fourteenth and fifteenth days. Testicle became more comfortable, but remained considerably enlarged. Urine on the fifteenth day showed numerous threads containing gonococci.

CASE 7.—Gonorrhœa 6 weeks; epididymitis 2 days, with considerable pain in vas deferens. Had previously suffered from metastatic gonococcal conjunctivitis, which cleared up under ordinary vaccine treatment. Intramuscular injections of 4 c.c., 5 c.c., 6 c.c., and 8 c.c. phylacogen on first four days. Pain in the vas disappeared after first injection, but returned on the fifth day, with increase of pain in the

epididymis. Intramuscular injections of 10 c.c. phylacogen on the sixth and eighth days were followed by great relief of pain. After five intravenous injections of 1 c.c. to 3 c.c. phylacogen during the succeeding week epididymis was free from pain, but about twice its normal size.

CASE 8.—Gonorrhœa three months. One month after infection commenced very severe epididymitis, which was treated with vaccine and puncture of the epididymis. Testicle had become practically normal, but phylacogen treatment was commenced on account of slight return of pain and swelling, threatening a relapse of epididymitis, and to observe its effect on persistent gleet. Intramuscular injection of 2 c.c. phylacogen was followed by disappearance of pain. Two days later intramuscular injection of 5 c.c. phylacogen, and during the following week five intravenous injections in doses rising by increments of 1 c.c. to a maximum of 3 c.c. At the end of this time a small nodule remained in the epididymis and gleet persisted, with gonococci as numerous in the discharge as before commencing injections with phylacogen.

CASE 9.—Gonorrhœa 2 months; epididymitis 1 month. Epididymis no longer tender, but generally hard and slightly enlarged. Urethral discharge containing gonococci. Phylacogen given to test its effect on the gleet and in hastening resolution of the epididymitis. Intramuscular injection of 5 c.c. phylacogen followed by three intravenous injections of 1 c.c. to 3 c.c., and then an intramuscular injection of 15 c.c. phylacogen. No apparent effect on gleet or epididymis.

CASE 10.—Gonorrhœa 5 weeks; epididymitis 3 weeks. Epididymis no longer painful, but hard and generally enlarged. Phylacogen given to test its effect in hastening resolution. Subcutaneous injections of 3·5 c.c. and 5 c.c., intramuscular injections of 6 c.c., 8 c.c., 10 c.c. and 10 c.c. on first, second, third, fifth, sixth, and eighth days. Five intravenous injections of 1 c.c. to 3 c.c. on succeeding five days. Progress towards recovery the same as in cases treated on ordinary lines.

CASE 11.—Gonorrhœa 18 months, with interval of freedom from symptoms for 12 months. Epididymitis 2 months, with muco-purulent discharge containing numerous gonococci. On commencement of phylacogen treatment epididymis slightly enlarged, but free from pain and tenderness. Urethral discharge persistent. Eight intramuscular injections of phylacogen on alternate days, commencing with 5 c.c. and increasing steadily to 20 c.c. No apparent effect on urethral discharge or in hastening resolution of epididymitis.

CASE 12.—Gonorrhœa 5 weeks. Gleet, with fairly numerous gonococci in discharge. Intramuscular injections of 3 c.c., 4 c.c., and 5 c.c. phylacogen on successive days; five intravenous injections, increasing from 0·5 c.c. to 3 c.c. during the following week, each of these being followed by marked reaction with severe headache. An attack of influenza then intervened and phylacogen was discontinued for a week. On resumption of phylacogen discharge still persisted, but disappeared after two further intravenous injections of 3 c.c. The disappearance of the discharge in this case may possibly have been due to the phylacogen, but sudden disappearance of urethral discharge at this stage of the disease is fairly common in cases treated by other methods.

CASE 13.—Gonorrhœa 3 weeks. Para-urethral abscess 1 cm. behind the glans penis 2 weeks. During this time the swelling had decreased from about the size of a butter-bean to that of a pea. Urethral discharge containing fairly numerous gonococci. Two intramuscular injections of 3 c.c. and 4 c.c. and eight intravenous injections of 0·5 c.c. to 3 c.c. phylacogen on successive days. At the end of this time the swelling was of the size of a grape seed, and the discharge was still present, with gonococci in approximately the same numbers as before commencing phylacogen treatment.

CASE 14.—Gonorrhœa 6 months. Slight urethral discharge containing scanty gonococci (about one pair in ten fields). Ten subcutaneous injections of phylacogen in doses increasing gradually from 1 c.c. to 5 c.c. on successive days, the larger doses being followed by severe local reaction. Discharge and numbers of gonococci apparently unaffected.

CASE 15.—Gonorrhœa 6 days; lymphangitis of the penis, with considerable pain in and swelling of the penis. Intramuscular injection of 7 c.c. and intravenous injection of 2 c.c. phylacogen on successive days were followed by no relief. Hot sitz baths were ordered. Pain was considerably easier on the third day; sitz baths were continued. Intravenous injections of 3 c.c. and 4 c.c. phylacogen on third and fourth days, by which time all pain and swelling had disappeared. Return of pain and swelling on the sixth day. Intramuscular injection of 10 c.c. phylacogen was followed by disappearance of pain. Urethral discharge continued unabated, with numerous gonococci. No phylacogen administered from the eighth to the fourteenth days, by which time discharge had become rather more profuse. Intramuscular injection of 10 c.c. phylacogen was given on the fourteenth day, followed by nine subcutaneous injections of 3 c.c. At the end of this time signs of abscess of the left lobe of prostate showed themselves in severe pain on micturition and a rapid rise of temperature to 104° F., and on the following day there was considerable pain in the right thigh and knee. Phylacogen treatment was discontinued as small doses had failed to avert the complications mentioned, and the patient was too unhappy to risk the addition of the severe reactions which follow larger doses of phylacogen. Ionisation of the thigh and knee with salicylic ions was followed by immediate relief of pain there, and four days later the prostatic abscess burst into the urethra.

CASE 16.—Gonorrhœa 2 weeks; acute prostatitis 4 days, with very severe pain and no sleep for two nights. Intramuscular injection of 5 c.c. phylacogen was followed by complete relief of all pain. At the same time the urine became loaded with pus. Phylacogen continued for one week with daily intramuscular injections in doses increasing to 10 c.c. It was then omitted for one week, at the end of which time the prostatic pain returned. An intramuscular injection of 10 c.c. phylacogen was again followed by complete relief of the pain. Subsequent progress uneventful.

It would appear from the above cases that in my hands phylacogen has been chiefly successful in relieving pain, and this was especially marked in the case of gonococcal arthritis. In this case also it appears to have hastened recovery, but the same cannot be said for its effect on urethritis and epididymitis, and I have not been able to convince myself that it has any particular therapeutic value in these forms of gonococcal infection. Possibly my lack of success has been due to errors in the administration of phylacogen. If so, I can only hope that others, profiting by my mistakes, may achieve greater success. As far as can be judged from such a limited experience, the effect of phylacogen in relieving pain seems to be more marked after large than small doses, and it is possible that this is because the former are followed by more febrile reaction, which, temporarily at any rate, inhibits the activity of the gonococcus.

I have made a large number of tests to ascertain whether the blood serum of patients suffering from gonococcal infections deviates complement in the presence of phylacogen as antigen, but by a method which is sufficiently delicate to demonstrate antibodies to ordinary gonococcal antigen in most cases of ordinary gonorrhœa I have failed to demonstrate antibody to phylacogen. Possibly this is because phylacogen contains antigen in such a weak dilution that it cannot be used as antigen in a complement deviation test. The presence of phenol in the commercial product puts a limit on the amount of it which can be used in a complement-deviation test, and it would be interesting to test it after concentration and in the absence of phenol.

RADCLIFFE INFIRMARY, OXFORD.—The Chancellor of the University of Oxford, Lord Curzon of Kedleston, will open the new buildings of the Radcliffe Infirmary on Wednesday afternoon, Nov. 26th, at 2.30 o'clock, after luncheon in the hall of Queen's College.

REPORT AND REMARKS ON A SMALL EPIDEMIC OF POLIOMYELITIS,

OCCURRING IN THE PRACTICE OF G. H. JONES, M.R.C.S. ENG., L.R.C.P. LOND., AND G. M. W. HODGES, M.B., B.S. LOND., OF DEDDINGTON, OXON.[1]

BY PAUL B. ROTH, F.R.C.S. ENG.,

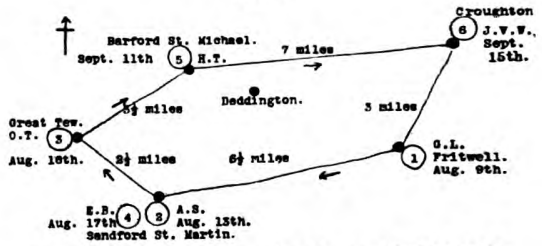
SURGEON, KENSINGTON AND FULHAM GENERAL HOSPITAL; SENIOR ORTHOPÆDIC CLINICAL ASSISTANT, LONDON HOSPITAL.

THIS epidemic consisted of six cases,[2] which occurred in five small villages around Deddington between August 9th and Sept. 15th, 1911. There was no death.

The sex, age, and order of attack of the cases are best shown in the following table:—

Case.	Age.	Sex.	Date of Onset.
1	8½ years	Boy	August 9th
2	1 10/12 ,, ...	,, ...	,, 13th.
3	9/12 year	,, ...	,, 16th.
4	4 years	Girl	,, 17th.
5	1 year	Boy	Sept. 11th.
6	10/12 ,, ...	,, ...	,, 15th.

Nature of onset.—Case 1: Occipital headache, head retraction and vomiting, temperature 103·2° F. Cases 2 and 3: Fever and vomiting. Case 4: Fever, headache, and vomiting. Case 5: Fever and drowsiness, temperature 101·4°, and according to mother headache. Case 6: Fever and restlessness, temperature 103–105°, and according to mother headache. Cases 1 and 6 may be regarded as severe cases, the others as slight ones. In all except one the acute symptoms lasted 2–4 days, and were then followed by pain and paresis; the pain in the affected limbs was a marked feature. As the pain and paresis developed the acute symptoms gradually subsided. In Case 6 there was pain for 6 days, and temperature 103–105°, after the appearance of paralysis. In Case 1 there was an unusual symptom, urinary retention.



Parts affected.—Case 1: Both legs, right shoulder, arm, and forearm. Case 2: Both legs. Case 3: Both legs and perhaps erectores spinæ. Case 4: Left leg, both forearms, right side of face, right external rectus causing internal strabismus. Case 5: Right shoulder muscles and sterno-mastoid causing typical wryneck. Case 6: Both legs and erectores spinæ.

Recovery (as observed in July, 1913).—Case 1: The right leg recovered to some extent, the shoulder girdle, arm, and left leg remaining the same. Case 2: Made an excellent recovery, but there is a fair amount of wasting in the left thigh. Case 3: Now has only slight foot-drop in one foot. Case 4: Made a perfect recovery with the exception of the face, in which, however, she lost the strabismus. Case 5: The sterno-mastoid recovered, but the shoulder muscles remain paralysed. Case 6: Made a good recovery; now "tends to trip with left foot owing to the slight foot-drop."

Remarks on the mode of infection.—The question of how the infection could have been conveyed in this epidemic is of interest.

Dr. Hodges says: "The cases were somewhat widely scattered, only Case 4 and Case 2 occurring in the same village, and these two lived under entirely different conditions and had never met. They were attacked only four days apart. It is certain none of the cases met each other before their attacks either at school or at school treats, nor had their parents met. The half-sister of Case 2, however, attended the same school as the family of Case 4." Dr. Hodges has made a rough diagram, which I have slightly altered (Fig. 1), to

FIG. 1.

Sketch map showing distribution of cases. The black dots indicate villages.

demonstrate the distances between the cases. A glance at it at once shows (1) the impossibility of direct infection in these cases; and (2) that the cases were affected one after the other in a circular manner.

In one of his letters to me Dr. Hodges wrote: "*The only point in their environment which is the same in all cases is the close proximity of stables.*" Thus in Case 1 there is a cattle-yard immediately behind the house; Case 2 lives in a lodge by the stable-yard of S—— Park; Case 3's father is a farmer; Case 4's father is a farm labourer; Case 5's father is a blacksmith; and Case 6 lives in a cottage with a stable immediately behind it.

That this environment may be of extreme importance is shown by the work of Dr. Milton J. Rosenau, of Harvard Medical School, whose experiments have been confirmed by John F. Anderson and Wade H. Frost.[3] They say:—

To summarise, three monkeys exposed daily to the bites of several hundred Stomoxys, which at the same time were allowed daily to bite two monkeys suffering from poliomyelitis caused by intracerebral inoculation, developed quite typical symptoms of poliomyelitis eight, seven, and nine days respectively from the date of their first exposure.

That is to say, they demonstrate conclusively that poliomyelitis can be transmitted from monkey to monkey through the agency of this fly. On inquiry I find that the fly Stomoxys calcitrans is also found in large numbers in this country, and in most inhabited parts of the world, tropical as well as temperate. Mr. Ernest E. Austen, of the British Museum (Natural History) writes[4]:—

(Stomoxys calcitrans)—a species often met with even in the centres of large towns, though commoner in the suburbs and found almost everywhere in the country[5]—is a blood-sucking fly which is sometimes mistaken for Musca domestica (the house-fly), with the result that the house-fly is occasionally alleged to have inflicted a bite, although its proboscis is merely adapted for sucking and is quite incapable of piercing the skin. Though agreeing with the house-fly in length, Stomoxys calcitrans is of a somewhat broader and more thick-set shape (see Fig. 2), and may readily be

[1] A paper read before the Orthopædic Subsection of the Royal Society of Medicine.

[2] Dr. Hodges writes: "At the time of this little epidemic there was to the best of my recollection and as far as I can gather from case-notes, no case of "influenza" in our practice. Another curious point was that we seemed to have a monopoly of poliomyelitis, none of the three other practitioners covering the district having a case."

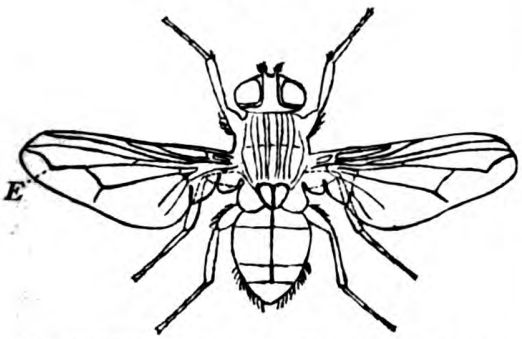
[4] The House-fly as a Danger to Health, 1913.

[5] The geographical range of Stomoxys calcitrans has not yet been fully elucidated, but it is undoubtedly very wide. The species is generally distributed in Europe, and also occurs in North America, where it is said to be very common throughout the inhabited parts. A race of it is found in the Gambia Colony, West Africa, and it has also been recorded as occurring in Hong-Kong, Batavia (Java), Ceylon, and Sydney (New South Wales). A specimen from the Naini Tal District, in Northern India, is indistinguishable from British examples. British Blood-Sucking Flies, by Ernest E. Austen, 1906, p. 59.

distinguished from Musca domestica (see Fig. 3) by the character of its proboscis, which is rigid and slender, and is always visible, projecting like an awl horizontally in front of the head. (Moreover) the fourth longitudinal vein in the wing of this fly, although somewhat bent up at the end, is not sharply elbowed as in the house-fly.

These flies breed in decaying vegetable matter, are found about stables and cowsheds, and are frequently to be seen in large numbers resting on gates and rails and fences. They are most prevalent in August and September. They attack human

FIG. 2.



Sketch of stomoxys calcitrans (female). From "The House Fly," C. Gordon Hewitt. 1910.

beings as well as horses and cattle.[6] The bite is a minute puncture inflicted by the proboscis.

Before giving any opinion on this matter there is one fact to which I must refer—the recent discovery at a place named Borna, near Leipzig, of a disease in horses which seems closely allied to poliomyelitis. This has been named the "Bornasche Krankheit"[7]; a similar disease in horses has also been described in other parts of Germany.

FIG. 3.

Sketch of house fly, musca domestica (female). E, elbow. From "The House Fly," C. Gordon Hewitt. 1910.

Conclusions.—The points to which I wish to direct attention are: 1. "That the infective material (in the laboratory) is very resistant to cold and the disease much more common in warm weather, and yet that the epidemics stop as soon as the cooler weather comes, would suggest that the infection is carried by some insect that is killed or disappears as soon as the summer ends."[8] 2. It has been proved that the disease can be transmitted from an infected monkey to a healthy monkey by the bites of the flies Stomoxys calcitrans. 3. These flies are found in all countries where epidemics of poliomyelitis have been described as occurring. 4. A favourite habitat of the flies is stables and cowsheds. 5. These flies bite horses and cattle and human beings. 6. A disease similar to poliomyelitis occurs in horses. 7. In the epidemic here reported the infection could not possibly have been direct. 8. There were *stables or cattle-yards* very close to the houses of the children affected.

From a consideration of these points I suggest that this epidemic was originated by infected Stomoxys biting Case 1 in the cattle-yard at Fritwell; that the infected patient was bitten by other Stomoxys which in turn became infected and were carried by horses or cattle, or on carts and wagons,[9] to the stableyard at Sandford St. Martin, where two more children were bitten and became infected, and so on through the other three villages. If this theory—viz., the transmission of poliomyelitis by the Stomoxys—should prove to be correct, not only for this particular epidemic, but for all other epidemics of poliomyelitis, then it should be possible, by a wholesale crusade against this species of fly, to banish the disease from large regions of the globe.

Notes of Cases.

CASE 1.—Male, aged 8½ years, father a farm bailiff, cattle-yard immediately behind house. Onset on August 9th, 1911; taken ill with severe occipital headache, head retraction, and vomiting; temperature 103·2° F. On the 11th the vomiting ceased and the headache was less, when there appeared weakness of both legs with much pain, both knee-jerks were lost, the right plantar reflex was flexor, and the left was absent. Kernig's sign was not present. Temperature 101·6°. On the 13th the boy was very ill. There was constant pain in both legs and the right shoulder, which had now become involved. The muscles chiefly affected appeared to be the extensor group of the thigh and the peroneal in the lower limbs, and the deltoid in the shoulder. Temperature 100·8°. There were retention of urine (catheter passed twice) and obstinate constipation only relieved by enemata. On the 15th the temperature was normal and the pain less; urine was passed naturally, and the bowels were opened with aperients. After-history: The boy gradually improved. In November the following muscles showed the reaction of degeneration—deltoid, coraco-brachialis, biceps, brachialis anticus, triceps, extensor carpi radialis, longior or brevior, in right upper extremity; hamstrings, quadriceps, adductors, tibialis anticus, and gastrocnemius in left lower extremity. He went to the Orthopædic Hospital at Birmingham, with the result that the right leg recovered to some extent, the shoulder girdle, arm, and left leg remaining the same.

CASE 2.—Male, aged 22 months, father a gardener, lives in a lodge by the stable yard of S—— Park. Onset on August 13th, 1911, with fever and vomiting. The child was first seen on the 18th, when there were paresis and pain in both legs, the muscles chiefly affected being the hamstrings on both sides and quadriceps of left thigh. The knee-jerks were absent, the right plantar reflex was doubtful, and the left extensor. After-history: The patient gradually made an excellent recovery, and he now walks well, but there is a fair amount of wasting in the left thigh.

CASE 3.—Male, aged 9 months, father is a farmer. Onset on August 16th, 1911, with fever and vomiting. On the

[8] Remarks by Professor Rudolf (Toronto) on Dr. F. E. Batten's paper read at Birmingham at the British Medical Association annual meeting, 1911, Brit. Med. Jour., Sept. 2nd, 1911, p. 492.

[9] It is unlikely that they could have flown such a distance. See An Experimental Investigation on the Range of Flight of Flies, by S. Monckton Copeman, M.D., F.R.S., F. M. Howlett, B.A., F.E.S., and Gordon Merriman, Reports to the Local Government Board on Public Health and Medical Subjects, New Series, No. 53. Quoted by Mr. Austen, loc. cit., 3.

18th there were pain and paresis of the quadriceps and hamstrings of both thighs. The knee-jerks were unobtainable; the extensors of the spine were probably involved. After-history: The patient gradually recovered, and now the left leg is half an inch shorter than the right, and there is slight foot-drop.

CASE 4.—Female, aged 4 years, father a farm labourer. Onset on August 17th, 1911, with fever, headache, and vomiting. On the 23rd she was first seen; she complained of pain in both forearms. There was paresis of the extensors of both wrists with double wrist-drop. Very marked right facial paralysis was also present, the orbicularis palpebrarum and muscles of the mouth being especially affected. There was some weakness of the left leg, but no pain. The right knee-jerk was normal and the left diminished; the right plantar reflex was flexor and the left extensor. Temperature 99·4° F. On the 26th right internal strabismus developed. On the 30th the left plantar reflex was flexor, but was obtained with difficulty. After-history: The girl gradually made a perfect recovery with the exception of the face, in which, however, the strabismus was lost.

CASE 5.—Male, aged 1 year, father a blacksmith. Onset on Sept. 11th, 1911, with fever and drowsiness, and the mother says headache. On the 14th the infant was first seen. There were pain and paresis of the right shoulder; the deltoid and sterno-mastoid appeared chiefly involved with typical wryneck. Temperature 101·4° F. After-history: The sterno-mastoid quickly recovered, but there remains paralysis of the deltoid, supra- and infra-spinatus, subscapularis, the upper part of the trapezius, and the coraco-brachialis.

CASE 6.—Male aged 10 months; stable immediately behind the cottage. Onset on Sept. 15th, 1911, with restlessness and fever, and the mother says headache. On the 18th, when the child was first seen, the hamstrings and quadriceps of both thighs were involved with much pain and also the erector spinæ. The pain was too severe to be sure of the knee-jerks. Temperature 104·2° F. The pain was very marked for the next six days, and the temperature remained at 103°–105°. After-history: Eventually the patient made a good recovery and now walks well, but tends to trip with the left foot owing to slight foot-drop. There is some slight wasting of the extensors and adductors of the thigh and the peronei of the leg on the left side.

I am much indebted to Mr. Jones and Dr. Hodges for permission to publish their cases, and to Mr. Austen for valuable assistance in the preparation of this paper.

Harley-street, W.

NOTES OF AN

OUTBREAK OF ACUTE ANTERIOR POLIOMYELITIS AT WEST KIRBY.

BY GEORGE JUBB, M.D. GLASG., D.P.H. OXON.,
ASSISTANT MEDICAL OFFICER, CHESHIRE COUNTY COUNCIL.

THE following cases of acute anterior poliomyelitis were discovered in West Kirby in 1912 and 1913, and as they present some remarkable features in their occurrence it was considered possible that their publication might be of general interest. I am indebted to Dr. J. B. Yeoman, medical officer of health for North-West Cheshire, for his kindness in giving me facilities for investigating the outbreak and permission to publish the results.

West Kirby is an urban district with about 6000 inhabitants, and it is a favourite seaside resort. It occupies a sheltered position at the north-west corner of the Wirral Peninsula. Its sanitary condition is good, it is well paved and well drained, there are a good water-supply, a water-carriage system of sewage removal, and efficient cleansing, dust being removed in covered bins, and there was found no evidence of undue accumulation of manure or other nuisance. Strict inquiries have been made, and no history can be obtained of any case of infantile paralysis having happened in the district prior to the present outbreak, the first case of which occurred on July 11th, 1912. The only antecedent condition which may possibly have some bearing on the origin of the infection was the arrival of a donkey in a verminous condition at the home of the first case. I append a brief history of the cases.

CASE 1.—Male aged 6 years. The illness began on July 11th, 1912, with sickness and pains in the legs. He was treated for rheumatism for a week, and then paralysis of the left leg was discovered. His brother, 5 years old, slept with him till the illness began. Three weeks before the boy's illness his father bought a donkey from Ireland for the children. When the donkey arrived the boy, his brother, and a cousin of the same age immediately climbed on its back and in consequence got a great number of lice on their clothes, as the extremely verminous condition of the animal had escaped notice. Their clothes had to be taken off and washed, and the donkey was clipped and cleansed; it was afterwards kept for three months in a field behind the house. The boy has been away from the district from the middle of May to Sept. 25th, 1913. His grandmother has a baker's shop in the same road.

CASE 2.—Female aged 2½ years. The illness began on July 6th, 1913, with headache. A medical man was sent for on the 8th, as she was delirious. Paralysis was discovered on the 10th, both hands and feet being affected; now the feet only are paralysed. This case is about 100 yards from Case 1, and the parents have a bread, cooked meat, and chipped potato business on the premises. Cases 3, 4, and 5 are customers and live quite near. There is also a connexion between Case 1 and Case 2, as the parents of Case 2 frequently get bread and yeast from the baker's shop associated with Case 1. There are other children aged 15, 13, 11, and 8 years in the house, in which there has been scarlet fever during last summer.

CASE 3.—Female aged 5 years. The illness began on July 28th, 1913, with sickness and vomiting. The child was able to go out on the 28th and 29th, but paralysis occurred on the 30th. This child went to the Presbyterian Sunday School, and its parents were customers of the shop associated with Case 2. Other children are aged 13, 9, and 6 years. There was scarlet fever in the house this summer.

CASE 4.—Male aged 1 year and 3 months. The illness began on August 1st, 1913, with drowsiness; on the 2nd there was headache. The child was ill for a week, and then a medical man was called in and diagnosed bronchopneumonia. At the end of another week it was discovered that there was paralysis of the legs. The other children are aged 13, 12, 9, 5, and 3 years, and go to the Presbyterian Sunday School. The parents are customers of the shop associated with Case 2.

CASE 5.—Female aged 1 year and 9 months. The illness began on August 14th, 1913; the child cried all day. Paralysis was discovered on the 17th. There are no other children. The parents are customers of the shop associated with Case 2. The child was taken to see the patient in Case 3 on August 2nd when this girl was ill.

CASE 6.—Female aged 6 years. The illness began on August 3rd, 1913. On the 4th she had pains in her head and dragged her left foot. On the 7th and 8th she complained of pains in her neck and legs. Both legs were paralysed and the right arm partially. On the 9th she went to a children's hospital. This case occurred about a mile from the previous cases, but in the immediate neighbourhood there are three shops (a baker's, a dairy, and a cooked meat shop) occupied by relatives of the proprietor of the cooked meat shop associated with Case 2. The dairy gets bread from the shop (Case 2) by means of a milk cart and horse. Other children are aged 16, 14, 12, 10, and 8 years. They go to the Presbyterian Sunday School, as do Case 3 and the brothers and sisters of Case 4.

CASE 7.—Male aged 1 year. The illness began on August 6th, 1913, with screaming. On the 9th there was a rash on the buttocks. On the 10th the child was unconscious, and there was retraction of the head, the arms being paralysed and the neck stiff. Other children are aged 11, 8, and 6 years. The father cleans the windows of the cooked meat shop mentioned in connexion with the previous

case as being in this district. This case is in the next road to Case 6.

CASE 8.—Female aged 4 years. The illness began on August 28th, 1913, with drowsiness, and squinting was noticed on the next day. The mother thought there was slight paralysis of the left leg. The child was in bed a fortnight only, and is now running about, but with a marked squint in the left eye. Other children are aged 14, 11, and 6 years. This case is across the road from the previous case.

I do not intend to enter further on the clinical features of the cases beyond drawing attention to the fact that the meningeal type prevailed. For the purpose of the present article the cases are more interesting from the epidemiological point of view.

It will be seen that there was a primary case in July, 1912, and as far as is known no others followed. During 1913 this primary case has been away from the district for treatment of his paralysis from the middle of May to Sept. 25th. Then there was a primary case in July, 1913, followed by three secondary cases in the same neighbourhood, and other three cases (one tertiary and two quaternary) grouped together about a mile away from the primary and secondary cases. It has been suggested to me that the incidence of these cases closely resembles an outbreak of typhus, and if so it seems reasonable to suspect that the spread of both diseases may be effected by means of the same agents—e.g., lice.

In Case 1 the mother definitely attributes the boy's illness to the arrival of the donkey, which, as has already been mentioned, was infested with lice, and it is interesting to note that in a great proportion of previous outbreaks of poliomyelitis there has been an apparent connexion with domestic animals. Seeing that Case 1 has been absent so long from the district this year it is probable that there was a carrier case which carried on the infection to 1913, and this might have been the younger brother if he had an abortive attack, or there may have been other atypical cases in 1912. According to Netter the serum of sporadic cases of poliomyelitis is active for two years, so that the infectivity of recent cases may be fairly prolonged.

There can be little doubt that Cases 3, 4, and 5 were infected from Case 2, though Case 5 might also have been infected from Case 3, which she visited. The infection *might* have been carried by means of flies, but as it is rather a poor neighbourhood it is just as likely that the infection was carried by means of lice.

Case 6 is the first in the third series, and she goes to a Sunday school in the district of the primary and secondary cases, attended also by Case 3 (who is about the same age) and by the brothers and sisters of Case 4. It seems probable that Case 6 was there infected and brought the infection to the new district. Cases 7 and 8 were probably infected from Case 6. There is, however, a direct communication between the two districts by a milk cart from the dairy near the tertiary case, which carries milk to the first district and brings back bread from the shop associated with Case 2. This would appear to be in favour of the theory of infection being conveyed by flies. It is worthy of notice, too, that with all the cases there was an apparent connexion with shops purveying food, and more especially bread. Their milk-supply was diverse and apparently therefore not concerned.

Transmission of the infective agent in poliomyelitis, whether it is a non-motile protozoon or not, certainly does not seem to be aerial, as in most of the West Kirby cases so many other children, presumably susceptible, were exposed to infection without developing the disease or showing signs of illness. In some of the cases other and younger children slept in the same bed with the patient up to the first day or two of the illness, and two of the cases were at an early stage transferred into different children's hospitals and nursed there, in the absence of any special precautions, without other cases arising. If the infection, then, is conveyed by a biting insect, it appears reasonable to suppose that it might just as easily be conveyed by the louse as by a biting fly, and in view of the suspicions raised regarding this possible mode of infection in the West Kirby cases it would seem desirable to secure and collect further information, where possible, bearing on this question.

Chester.

TWO CASES OF ASCITES TREATED BY MULTIPLE PARACENTESIS AND BY FEMORAL DRAINAGE.

BY W. GIFFORD NASH, F.R.C.S. ENG.,
SURGEON TO THE BEDFORD COUNTY HOSPITAL.

THE two cases of ascites here reported present several points of interest, and may for that reason merit a place in the columns of THE LANCET.

CASE 1. *Ascites treated by paracentesis, omentopexy, and femoral drainage.*—The patient, aged 48, a servant in a public-house, was admitted to the Bedford County Hospital on April 29th, 1909, suffering from ascites. She had had two miscarriages at the age of 20, and when about 25 years old she had syphilis, for which she was under treatment for several months. She was then and for several years afterwards a domestic servant. Later she became a barmaid, but denies that she ever drank much alcohol, sometimes going for days without any. Her beverage was stout. For the last seven years she was nearly an abstainer. In 1905 her periods ceased and her abdomen began to swell. Early in 1908 she states that she was in the Samaritan Hospital, London, for three weeks suffering from ascites. Nothing was done. In August of the same year she went into St. Bartholomew's Hospital and was tapped, 14 pints being removed. In January, 1909, at the same hospital 20 pints were drawn off. When she left St. Bartholomew's Hospital she weighed 8 st. in her dressing-gown. She went to her home in Bedfordshire, where on March 26th, 1909, spontaneous rupture occurred at the umbilicus and 30 pints of fluid escaped. The flow continued for a fortnight.

On admission on April 29th, 1909, the abdomen measured 48 inches at the umbilicus. The liver was displaced upwards as high as the fourth rib. There was a soft swelling, 3 inches in diameter, attached to the lower ribs in the mid-axillary line. This was diagnosed as a gumma, and a mixture containing mercury and iodide of potassium was ordered. Paracentesis of the abdomen was performed on the following dates: May 2nd, 1909, 41½ pints; May 23rd, 32 pints; and June 13th, 33 pints. On June 15th the abdomen was opened above the umbilicus and omentopexy performed. There were perihepatitis and perisplenitis. The liver was about the normal size and contained numerous gummata. The spleen was much enlarged and also contained gummata. After this operation the ascites recurred and parencentesis was performed as follows: July 4th, 16 pints; July 25th, 19 pints; August 15th, 18 pints; Sept. 5th, 9 pints; and Sept. 26th, 9 pints. On Sept. 29th she was discharged from hospital and no further medicine was taken.

She returned for paracentesis as follows: Oct. 28th, 1909, 13 pints; Dec. 15th, 14 pints, and on Feb. 18th, 1910, 11 pints. On Feb. 25th a bone bobbin was inserted in the right femoral canal, incisions being made in the middle line of the abdomen and in the femoral region. The wounds healed without any leakage. In all the patient was tapped 14 times and 280 pints of fluid were drawn off.

The patient was examined on March 21st, 1911, exactly a year after leaving the hospital. She looked in excellent health and weighed in her clothes 12 st. 2 lb. The swelling on the ribs had disappeared. There was no ascites. The liver could not be felt, but the spleen was considerably enlarged. No trace of the bobbin could be felt. She was seen on Oct. 25th, 1913, when there was no return of ascities. Her spleen was enlarged, her weight 11½ st., her health was excellent, and she was earning her living as a housekeeper and barmaid.

CASE 2. *Cirrhosis of liver; ascites; femoral drainage; recovery.*—The patient, a barman, aged 43, was admitted to the Bedford County Hospital on March 27th, 1912, suffering from ascites. He had enjoyed good health until Christmas, 1911, when he became jaundiced and his legs and abdomen swelled. He was admitted to St. George's Hospital, London, and tapped on the following dates: Jan. 23rd, 1912, 5 pints; Feb. 6th, 14 pints; Feb. 20th, 16 pints; March 4th, 12 pints; and March 15th 15 pints. There was no ascites when he was admitted to St. George's Hospital, but it developed within a fortnight. He was very ill when he left St. George's and was advised to go to an infirmary.

On admission, under my care, he was jaundiced, the abdomen was much distended, and the legs were swollen. He had considerable dyspnœa. He denied any history of syphilis, and no sign of it could be found. On March 27th he was tapped and 30 pints of fluid evacuated. The liver was then felt enlarged to midway between the costal margin and the umbilicus. Small nodules studded its surface, with one large one in the gall-bladder region. On April 11th the abdomen was again tapped and 17 pints removed. On the 12th a bone bobbin was inserted in the right femoral canal. Owing to re-accumulation of fluid and to prevent tension on the wound the abdomen was tapped on April 21st and 12 pints drawn off. On May 3rd 11 pints and on the 12th 9 pints were withdrawn. On July 13th he left the hospital. There was then no ascites, the liver was still the same size, and there was slight jaundice. From April 1st until he left the hospital a mixture containing mercury and iodide of potassium was given.

On Oct. 27th, 1912, there was still slight jaundice, the liver showed no change, and there was a slight trace of fluid in the abdomen. On Oct. 23rd, 1913, he reported that he was quite well, with no abdominal swelling or jaundice, and that he had returned to work as a barman in the previous July.

In the first of these cases syphilis probably was the main factor in producing the ascites, as there was a distinct history of the disease and the presence of the gumma on the ribs and gummata in the liver and spleen. The occupation of the patient made one suspect alcohol as an additional cause.

In the second case there was no evidence of syphilis except the rather large nodule in the region of the gall-bladder. The occupation and appearance of the man suggested alcoholism. The presence of jaundice and œdema of the legs were also in favour of alcoholic cirrhosis. The fact that the man recovered after repeated tappings and operation is against pure alcoholic cirrhosis, as Rolleston and Hale White[1] are of opinion that such cases seldom survive more than one or, at the most, two tappings. Spontaneous rupture at the umbilicus must be a very rare event, as many authors do not even mention its occurrence.

Alcoholics are such notorious liars that it is very difficult to obtain a history of syphilis, and syphilis may have occurred without leaving any trace behind. It appears to be quite justifiable to try antisyphilitic remedies in any case in which the patient with ascites (due to liver disease) survives two or more tappings. The introduction of a bone bobbin into the femoral canal was originally suggested by Dr. W. Essex Wynter.

Bedford.

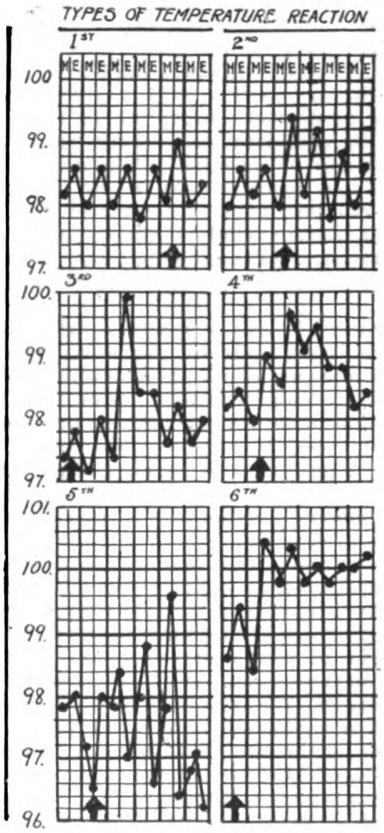
POLYVALENT TUBERCULIN AND THE TYPES OF TEMPERATURE REACTION; A NEW TECHNIQUE.

BY HALLIDAY SUTHERLAND, M.D. EDIN.,
FELLOW OF THE ROYAL SOCIETY OF MEDICINE; MEDICAL OFFICER TO THE ST. MARYLEBONE TUBERCULOSIS DISPENSARY.

THE design of tuberculin treatment is to induce in the infected organism a general immunity to the toxins of tuberculin in the hope that this will be associated with a relative immunity to the living tubercle bacillus. Immunity to tuberculin does not always mean immunity to tuberculosis. Theoretically the problem is as follows. If tuberculin were identical with the living tubercle bacillus, how should an organism infected with the latter give an immunising response to the first? Again, if the two were entirely different an immunity to the one would not represent an immunity to the other. Therefore, the more a tuberculin corresponds, without absolute similarity, to the infecting tubercle bacillus the more likely is an immunity to tuberculosis to be attained. The late Professor Arloign, of Lyons, used an attenuated living culture to immunise bovines against a lethal dose of a virulent culture. Webb, of Colorado, has injected small quantities of an attenuated living culture of human tubercle bacilli into children. In general vaccine treatment autogenous vaccines have been found most useful. Tuberculins contain either the exotoxins or the endotoxins of the tubercle bacillus. It is possible that a tuberculin might raise the immunity to the endotoxins without affecting immunity to the exotoxins. All who have worked with tuberculin have obtained excellent results in some cases and indifferent results in others. This might be due to the tuberculin employed not sufficiently approximating in its chemical constitution to the tuberculous toxins in the patient's system. On these grounds I began to use in October, 1911, a polyvalent tuberculin of the following constitution in each cubic centimetre—tuberculin Koch, 0·025 c.c.; bovine tuberculin, 0·025 c.c.; vacuum tuberculin, 0·025 c.c.; bovine vacuum tuberculin, 0·025 c.c.; tuberculin T.R., 0·05 c.c.; bovine tuberculin T.R., 0·05 c.c.; bacillary emulsion, 0·033 c.c.; bovine bacillary emulsion, 0·033 c.c.; polygenous bacillary emulsion, 0·034 c.c.; T.O.A., 0·35 c.c.; and P.T.O., 0·35 c.c. (Prepared for me by Messrs. Allen and Hanbury.)

Preparation of dilutions.—Nine dilutions are made from the pure polyvalent tuberculin by measuring 18 c.c. of 0·8 per cent. sterile NaCl solution into sterilised glass-stoppered bottles marked D_1, D_2, D_3, D_4, D_5, D_6, D_7, D_8, and D_9. To the solution marked D_1 add 2 c.c. of pure polyvalent tuberculin and mix well. By adding 2 c.c. of D_1 to the saline solution in the second bottle D_2 is prepared, and so on. Each dilution is thus ten times weaker than its predecessor. The dilutions are made in the cold. With ordinary asepsis they retain their properties for two to three weeks. When the pure tuberculin and its dilutions have stood for some hours the bacterial débris settles as a fine precipitate. If the solution be gently rotated this débris rises like a thin, curling column of white smoke into the supernatant fluid, and forms a perfect emulsion. After two or three weeks the débris in the dilutions will become agglutinated, when fresh dilutions must be prepared. The pure polyvalent tuberculin will retain its properties for



several months. Bacterial contamination of the solutions is indicated by small, round, white, fluffy growths or by surface moulds.

Cases suitable for tuberculin.—It is impossible to consider the selection of cases in terms of a purely anatomical classification (Turbans), and the question is best discussed on the basis of a clinical classification such as Philips's. The following groups are suited for tuberculin treatment. The early tuberculous infections of childhood, as represented by L_1 and L_2, are given tuberculin as a prophylactic. In old arrested lesions, indicated by L_3, tuberculin is employed to prevent a relapse. In L_1s and L_2s we have cases where the active onset is recent, systemic intoxication slight; and again, there are the old-standing chronic cases with little systemic disturbance, represented by L_3s. All these do well on tuberculin. By L_1S we mean early local disease with equivalent systemic intoxication, which should be combated by rest in bed, and when the large S has been converted into a small s, tuberculin may be given either at home or at a sanatorium. In the same way L_2S and L_3S may be treated with tuberculin.

Precautions of administration.—The patient must chart his temperature, and is required to record on his chart the pulse-rate and the daily amount of sputum. Female patients should draw a black line on the chart during the menses, as the menstrual rise might simulate a reaction. Pregnancy is not a contra-indication, even with a slight degree of albuminuria. The temperature should be taken at 8 A.M., 4 P.M., and 8 P.M. While rectal temperatures are most accurate, it is difficult outside a sanatorium to get ambulant patients to take their temperatures in this way, and in these cases axillary temperatures are more reliable than readings in the mouth. Injections are made with a German Record syringe, platinum iridium needle, graduated to 1/50th c.c. The syringe is washed out before and after each injection with pure ether, and the patient's skin may be wiped with ether. The injections are made subcutaneously on the anterior aspect of the upper arm about the middle of the biceps, where the skin is least sensitive and one is able to avoid veins and nerves.

The principles of dosage.—The dose of tuberculin is gradually increased on the assumption that the more the patient can tolerate with safety the greater is the immunising response. A mechanical dosage is impossible since the optimum dose will depend on the patient's condition, and a dose of tuberculin is large or small, according to its relation to the degree of systemic intoxication. The geometrical progression I have found most serviceable is the quarter, and the ten doses in each solution are 0·13 c.c., 0·16 c.c., 0·2 c.c., 0·25 c.c., 0·32 c.c., 0·4 c.c., 0·5 c.c., 0·63 c.c., 0·79 c.c., and 1 c.c. The injections are given once or twice a week according to the patient's condition, and the initial dose is usually D_6 1 c.c. or D_7 1 c.c. The correct dose will adjust the balance on the side of immunity by the relation of the amount of tuberculin injected to the general condition of the patient, of which the first is under our control, while the second may be measured by clinical methods. The early case of slight severity allows a wide margin for error, and to this I attribute not only the brilliant results of careful treatment, but also the benefit which has occurred in spite of haphazard methods. In advanced disease the conditions are very different. The patient is being poisoned by massive doses of toxin from his own system, and the mechanism of immunity is almost in full abeyance. It is reasonable to presume that the dose of tuberculin should be reduced to meet a lowered vitality, so long as sensitiveness is still present. This may be partly judged by the local reaction, and I have seen a marked local reaction follow an injection of $D_{10}1$ c.c., polyvalent tuberculin, or 1/10,000,000,000th of a cubic centimetre. In cases of advanced disease with secondary infection these infinitesimal doses may be combined with the administration of an autogenous vaccine.

The types of temperature reaction.—The general reaction to tuberculin includes a group of symptoms referable to the toxic properties of this agent on the neuro-muscular systems. These symptoms are of major clinical importance since they are produced by a smaller dose than will cause a focal reaction. Of the whole group the temperature reaction is the key to successful treatment. None will deny that the failures of the early tuberculin era were due to ignoring temperature reactions. While that is generally admitted, the error continues of referring to reactions as if they

differed in degree but not in type. From a failure to differentiate between the types of temperature reaction, two rival schools of the reaction and the reactionless method have arisen. The absolutely incompatible theories, the contradictory published results, the general confusion of thought in the mind of the profession generally, require no recollection. The truth of the matter is that both schools are right. There are some reactions which all may disregard with impunity. There are others which no intelligent physician will dare to overlook. I also suggest that in these types of temperature we have an accurate and scientific indication as to dosage. (See chart.)

Before proceeding to describe these types it is postulated that a rise of temperature, even of half a degree Fahrenheit above the mean, occurring within 72 hours of an injection of tuberculin is to be regarded as a reaction. A rise of temperature reaching its maximum within 24 hours of an injection is an *immediate reaction*, and may occur four hours after the injection. A rise of temperature reaching its maximum within 48 hours of the injection is a *delayed reaction*. A rise of temperature reaching its maximum within 72 hours of the injection is a *progressive reaction*. Now, since all pyrexia must resolve either by crisis or by lysis, it is clear that there may be six types of reaction. This is confirmed by observation.

1. *An immediate reaction with a fall by crisis.*—This, the mildest form of reaction, is due to the tuberculin injected, which is followed by complete immunising response. From the point of dosage it is of least significance, since the dose may be later increased and no reaction occurs.

2. *An immediate reaction with a fall by lysis.*—Here, in addition to the immediate reaction to the tuberculin, there are secondary oscillations due to incomplete immunising response. At the next injection the dose should be reduced by one-fifth the amount—that is to say, from 0·5 c.c. to 0·4 c.c.

3. *A delayed reaction with a fall by crisis.*—In this there is delayed absorption of the tuberculin followed by complete immunising response. The same dose may be repeated at the next injection.

4. *A delayed reaction with a fall by lysis.*—Here there is not only delayed absorption of the tuberculin, but an incomplete immunising response. The amount next injected should be reduced to one-half of the previous injection—e.g., from 0·79 c.c. to 0·4 c.c.

5. *A progressive reaction with a fall by crisis.*—In this there is not only an immediate reaction, but increased toxæmia from a focal reaction, eventually overcome by immunisation. This is the type of most serious significance, and if not regarded it will be followed by a violent summation temperature or by a gradual and persistent pyrexia, due to prolonged focal reaction. The dose of tuberculin must be reduced to one-tenth at the next injection —from $D_{\frac{1}{2}}$1 c.c. to $D_{\frac{1}{1}}$1 c.c.

6. *A progressive reaction with a fall by lysis.*—Here a focal reaction is not overcome by immunisation. The disease is lit up in the pulmonary lesion, and may progress by secondary tuberculous bronchopneumonia, of which this temperature is typical. Tuberculin treatment must be stopped, as otherwise the patient will pass into a condition of chronic tuberculous cachexia. The example of this type illustrated in the temperature chart occurred in my practice before one had appreciated the significance of the fifth type as a warning.

In their order of severity these types of temperature reaction are as follows: *a*. Immediate reaction with a fall by crisis—increase dose. *b*. Delayed reaction with a fall by crisis—repeat dose. *c*. Immediate reaction with a fall by lysis—reduce dose by $\frac{1}{5}$. *d*. Delayed reaction with a fall by lysis—reduce dose by $\frac{1}{2}$. *e*. Progressive reaction with a fall by crisis—reduce dose to 1/10. *f*. Progressive reaction with a fall by lysis—stop tuberculin.

Results of treatment.—The following are the immediate results of treating 131 patients, ambulant cases, with polyvalent tuberculin on these lines at the St. Marylebone Tuberculosis Dispensary. The record does not include patients who received prophylactic injections. The time of treatment varied from 3 to 25 months. I have used Philip's classification, and a division is made between those whose sputum contained tubercle bacilli and those in whose expectoration the tubercle bacillus was not found. The word "cure" is avoided, but the words "disease arrested" implies that the patient presents neither symptoms nor any signs of active disease.

Allsop-place, W.

TUBAL GESTATION CONTINUING TO THE SIXTH MONTH AFTER RUPTURE AT THE SIXTH WEEK.

BY ROBERT NAIRN, F.R.C.S. ENG., L.R.C.P. LOND.

THE following is an account of a condition which is perhaps sufficiently rare to deserve publication in THE LANCET.

The patient, who had been married for six years, had had no children. The cervix was long and narrow, with a small os; the os had been twice dilated. Menstruation had always been painful at first, but it was regular. When seen on Jan. 25th, 1912, the patient complained that after missing one period menstruation had now gone on for nearly three weeks. Her last period had been on Nov. 24th, 1911. On Jan. 7th, 1912, menstruation began with an unusual amount of pain, especially inside the right hip. There were numerous blood clots. This lasted for about three days; it then stopped, and she felt well till Jan. 11th. She then had violent pains which lasted until the following day, when there was free bleeding for about an hour. It was not pure blood that came away, being very pale, like blood mixed with water. On the 13th there was a little "blackish" blood passed, and since then there had been a constant discharge of brownish matter.

On examination the breasts were found to be rather full, and they were slightly painful. The uterus was tender and immovable, with thickening all round it, and a brownish purulent discharge from the os. The temperature was 100·4° F. A diagnosis of miscarriage with subacute parametritis was made. On Jan. 26th the patient was curetted and given hot douches frequently. The curette went in rather to the patient's left. The discharge almost stopped after this, and the temperature remained normal until Feb. 18th, when it rose to over 100°, and the discharge increased, though it was lighter in colour. Hot douching was continued for four weeks longer, after which the temperature remained normal and the discharge stopped entirely. There was still tenderness, with a feeling of thickening about the uterus. On March 21st the patient felt quite well. On examination there were still immobility and matting about the uterus, which had enlarged to the right of the middle line, and a uterine souffle was heard. The breasts had

distinctly enlarged. An amended diagnosis of either double pregnancy in a bicornuate uterus with miscarriage from the left cornu (normal or ruptured ectopic pregnancy) or fibroid of the uterus with miscarriage was now made. The uterus and breasts continued to enlarge through April and May, and the former was nearly up to the umbilicus.

Early in June I again examined the patient and found that the uterus had not continued to rise, and that the souffle was less distinct. Towards the end of June it was evident that the uterus had sunk. There was no souffle and the breasts were smaller.

When again examined on August 3rd a solid mass was felt per vaginam to the patient's right, but matting made it impossible to differentiate the parts. In view of the doubt as to the true condition a laparotomy was decided upon, and this I performed on August 8th, assisted by Dr. W. W. Moore and Dr. MacDonell. On examining the pelvis through the median incision the uterus and left ovary were found to be adherent to the left side. The right broad ligament was obliterated by a large fluctuating swelling in its substance, filling the pelvis; and the right ovary and extremity of the Fallopian tube were defined on the surface of this swelling. An incision parallel to the pelvic brim let out a great quantity of dark brown fluid, together with what appeared to be a five-months' fœtus with fair-sized placenta.

It was evident that a right tubal pregnancy had ruptured beneath the peritoneum at about the sixth week, and gestation had then progressed until about the sixth month, when it was stopped by want of sufficient blood supply. Convalescence was slow, but eventually the patient recovered perfectly.

Hastings, New Zealand.

THE DIAGNOSTIC VALUE OF ABDERHALDEN'S METHOD IN CARCINOMA.

BY R. ST. LEGER BROCKMAN, M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEON AT ST. BARTHOLOMEW'S HOSPITAL.

Abderhalden, professor of physiology at Halle in Germany, in his work on ferments of the animal system has shown that the body has the power to protect itself against substances which are foreign to it if introduced by subcutaneous or intravenous methods. The injection of cane sugar and vegetable proteids will give the serum of a dog into whose system they are so introduced the power of breaking down these substances into less complex molecules—a faculty wanting in the serum of an animal not so injected.

After Veit had shown that syncytial cells were present in various parts of the body during pregnancy Abderhalden set to work to see if he could show that any attempt was made to defend the body against such invasion, especially as the toxæmias of pregnancy were being attributed to syncytiotoxins. In 1912 he published articles describing the means by which he and his pupils had been able to demonstrate in the blood of a pregnant woman the presence of a substance which has a proteolytic action on placental albumin. He also showed that such a substance is absent from the blood of males and non-pregnant women, and further that this ferment is specific, acting on placental tissue only. To do this he made use of two methods—the dialysation method used in the following cases, which will be described later, and the optical method. In this latter case 1 c.c. of a 10 per cent. solution of placental peptone and 2 c.c. of serum from the patient under question are placed in a small polarimeter tube, the initial degree of rotation of light being at once read off. The tube is now placed in an incubator at 37° C., the tube being removed occasionally and examined by means of a polariscope. Incubation was allowed to proceed up to 36 hours. Abderhalden found that the maximum change of rotation with serum from a case of pregnancy was as high as 0·2°, whilst that when any other serum was used never exceeded 0·03°. His experiments in the case of animals gave similar results. The practical value of such methods in the diagnosis of pregnancy has been testified to by Abderhalden, Veit, Schwarz, and other observers.

The object of the present paper is to show that a specific ferment is formed against carcinomatous tissue, and to demonstrate the possibility of the existence of such being made use of in the diagnosis of carcinoma. In all the following cases the dialysation method of Abderhalden has been used.

A piece of coagulated carcinoma tissue, the preparation of which is described later, is placed in a dialysing tube, made from a fish's swim-bladder. To this are added 1·5 c.c. of serum obtained from the patient whose diagnosis is in question. Outside the dialysing tube are 20 c.c. of sterile distilled water. Into a control tube are put 1·5 c.c. of serum alone, from the patient, with 20 c.c. of distilled water outside. The surface of serum and water in both cases is covered with a thin layer of toluol to exclude as far as possible all bacterial contamination. They are now incubated at a temperature of 37° C. for 12 to 24 hours. At the end of that time 10 c.c. of the diffusiate in each case are added to 0·2 c.c. of a 1 per cent. solution of a reagent known as ninhydrin. (Ninhydrin, or triketohydrindene hydrate, with a formula $C_6H_4\begin{matrix}CO\\CO\end{matrix}C(OH_2)$, gives a violet colour if heated with a solution containing minute traces of albumin, peptones, polypeptides, and amino-acids. It gives a reaction with all substances in which the amido group is in α position to carboxyl.) The solution is raised to the boiling point and maintained at that temperature for one minute. If at the end of that time no change takes place in either case the test is negative. If, however, in the case of the one containing carcinomatous tissue a violet colour results whilst the other remains colourless, then a positive result has been recorded. In many cases a brownish tint remains after boiling. This has no connexion with the unmistakable violet colouration of a positive result.

The coagulated cancer tissue was the same for all the following cases. It was obtained from a woman with a large spheroidal-celled carcinoma of the breast. As soon as the breast had been removed by a complete Halstead operation the carcinoma was carefully separated from fat and breast substance. It was then cut up into small pieces which were dropped bit by bit into a beaker of boiling distilled water to which a few drops of glacial acetic acid had previously been added. It was boiled thus for half an hour. The tissue was then washed carefully in distilled water for 12 hours. It was kept ready for use in cold storage in dis-water tilled with a layer of toluol on top. Before any was used it had been kept thus for three weeks. The water in which it had been standing was then tested with ninhydrin with a negative result, thus showing that all the albumin had been efficiently coagulated. It was then dialysed with water, saline, and healthy human serum severally. The diffusiate in all cases gave no reaction with ninhydrin. The presence of dialysable products, sufficient to nullify the test, in this cancer tissue was thus excluded. The dialysing tubes were then tested as regards their permeability to peptones and their impermeability to colloids. Those which fulfilled these conditions were then used for the tests—all others being rejected. In referring to certain pitfalls and sources of

error which await one in doing this test I will describe the method employed in collecting the serum in these cases.

In the first place the fingers must be absolutely excluded from any direct part in the test. A drop of ninhydrin on the skin, especially if at all moist, will leave a deep violet stain. The contamination of the outer side of a tube with a finger, prior to dialysis, is sufficient to give a positive reaction on testing the diffusiate with ninhydrin. A pair of sterile forceps was used in these cases to lift tubes and tissue.

A trace of saliva will equally well give a positive reaction. This means that the mouth ought not to be used for suction whilst using a pipette. I use a rubber bulb on the end of my pipettes, though probably a plug of cotton-wool in the end of the pipette is sufficient to prevent contamination in this way. Absolute asepsis must be observed. Air-borne organisms such as B. subtilis and B. mesentericus do not, so far as my experiments go to show, nullify the test in 48 hours, but S. pyogenes aureus and, to a lesser extent, S. epidermidis albus will, even in the presence of toluol, cause sufficient change in the serum with the subsequent passage through the dialyser of the breakdown products in 24 hours, thereby rendering the result of no value. This can be understood when the liquefying action of these organisms is remembered. The presence also of hæmoglobin in the serum renders that sample utterly useless for working the test.

In these cases the blood was taken with all the precautions adopted in doing a blood culture. It was collected by means of a syringe, transferred to a sterile tube, and centrifuged at once. The serum was then drawn off and used for the test without any delay. The serum ought to be clear and straw coloured. The opalescent serum obtained from a patient shortly after a heavy meal is not reliable, since it contains dialysable substances which give a positive result in the tube containing serum alone, so that the colour obtained in that with carcinoma tissue may also be due to the same cause.

In some cases at the beginning I put my blood into cold storage to allow the separation of serum to take place. The serum so treated gave negative results, whilst serum from the same patients if used fresh gave a strongly positive result. This ferment appears to be specific for cancer tissue. Serum giving a positive reaction with carcinoma tissue gave a negative one if placental tissue or egg albumin was used. It is specific for cancer tissue in general, but will work equally well in all varieties of carcinoma, as will be seen from the following list of cases. In the first place I did the test on 25 cases which were undoubtedly carcinoma, and then on 20 odd cases in which carcinoma could be excluded beyond reasonable doubt, and in two cases beyond all doubt, as they subsequently found their way to the post-mortem room. The test was positive in all 25 cases of carcinoma and negative in the controls. In one case, which section has proved to be a carcinoma of the larynx, a negative result was recorded, possibly because only 16 hours were given for incubation.

Twenty-five Cases of Carcinoma.

Position of growth.	Number of cases.	Confirmed by section.	Nature of growth.
Tongue	6	3	Squamous celled.
Breast	5	4	Spheroidal celled.
Stomach	3	1	Columnar celled.
Bowel	2	2	Squamous celled.
Cervix	3	1	,,
Rectum	2	1	Spheroidal celled.
Testis	1	1	—
Urethra	1	1	—
Gall-bladder	1	0	—
Larynx	1	0	—
Totals	25	14	

As can be seen from this list 14 were confirmed by section, the nature of the growth in these cases all being recorded. Of the other cases the tongues were inoperable with secondary glands, the remaining breast was a cancer *en cuirasse*. The stomach cases were proved by clinical signs, test meals, and laparotomy. The carcinomas of the cervix were inoperable, a laparotomy being performed in one case. The rectum, the gall-bladder with jaundice, and the larynx with secondary glands necessitating tracheotomy were clinically undoubted cases of carcinoma. In all these the test was positive.

To place against these are the controls which gave negative results. So far I have not had a patient without carcinoma who has given a positive result. The controls include healthy patients and those with fractures, septic hands, tertiary syphilitic and tuberculous ulceration. There are some other doubtful cases which have not yet been proved by operation, post mortem, or subsequent history.

In addition there are a few cases which I thought worthy of individual notice. For permission to publish these I am indebted to the various members of the clinical staff at St. Bartholomew's Hospital.

CASE 1.—A man, aged 66, was admitted under Mr. H. J. Waring complaining of stoppage of the bowels. He gave a history of increasing difficulty in getting his bowels open. The calibre of his motions had got decidedly smaller. There was no history of passage of blood or mucus. For five days he had passed neither fæces nor flatus. A colostomy was performed, an annular stricture of his pelvic colon being found. This was freely movable, and on subsequent resection proved to be a columnar-celled carcinoma. *Test positive.*

CASE 2.—A woman, aged 52, was admitted under Dr. Herbert Williamson, complaining of abdominal pain. On examination a tumour was felt rising out of the pelvis to the level of the umbilicus. Per vaginam the pelvis was occupied by a fixed mass which could not be differentiated from the abdominal swelling. There was marked œdema of one lower extremity. The patient was thin and anæmic. The diagnosis was made of ovarian cyst (? malignant). A laparotomy was performed and the swelling removed. A section showed it to be a papilliferous ovarian cyst in a degenerated condition, but with no evidence of malignancy. Subsequent to the operation the œdema of the leg has completely disappeared. *Test negative.*

CASE 3.—A man, aged 32, admitted under Mr. C. Gordon Watson with a swollen left testicle. He gave a history of enlargement of the left testicle for two years, with a rapid increase in size for two months previous to admission. A hydrocele on tapping yielded clear serous fluid. The swelling was painless and testicular sensation was lost. Wassermann was negative. The testis was removed and section showed it to be a carcinoma. This patient has been seen since and now has a local recurrence. *Test positive.*

CASE 4.—A woman, aged 34, was admitted under Mr. W. McAdam Eccles complaining of a swelling of the umbilicus. Beyond slight induration around the navel nothing could be felt. A piece removed for section showed the structure of a simple adenoma with no evidence of malignancy. A laparotomy revealed a large mass in the stomach with a secondary swelling on the deep surface of the umbilicus, which section showed to be a columnar-celled carcinoma. *Test positive.*

Conclusions.—There is here, I think, sufficient evidence to show that the blood of persons suffering from carcinoma contains a substance absent in the blood of all others, and that this substance has a proteolytic action on the carcinoma tissue only. There are also several factors which point to its being of the nature of a ferment. If the serum from a patient is left to get stale it becomes inactive, but the addition of a trace of fresh human serum will activate it again. The reaction takes place best at 37° C. At room temperature the reaction does not occur, whilst heating the serum to

55° C. for five minutes inactivates it beyond recall. If, then, as is maintained, this substance is of a protective nature it would be natural to expect to find it present in larger quantities in patients who were in good general health. The results of these tests point strongly to such being the case. I have noticed throughout the whole series that a patient with a growth of the tongue or of the breast who is in good general condition will give an intensity of colouration in 12 hours which a patient in a low state of health would fail to give in 24.

The case of carcinoma of the larynx which gave a negative result only brings this test into line with others. No pathological test known to us is infallible. It is obvious that for practical use such a test must give a reaction in the early stages of the disease. Two of the tongue cases were early localised ulcers, one intestinal growth was small and easily removable, whilst one breast case was an early scirrhus. All these gave a markedly positive reaction in 24 hours.

The facts set forth here do, I think, point to the test being of some practical advantage as an aid in the diagnosis of carcinoma, especially in such sites as the stomach and bowels, thereby allowing early surgical interference. These results have all been obtained working in the pathological laboratory of St. Bartholomew's Hospital, where the kind suggestions of Dr. Mervyn H. Gordon and Mr. Mackenzie Wallis have always been at hand.

(Since writing the above, corroborative results have been published by some German observers. Gambaroff has gone a step further and maintains the possibility of differentiating between sarcoma and carcinoma by this method.)

A NOTE ON FIVE CASES OF POROCEPHALIASIS IN MAN FROM SOUTHERN NIGERIA.

BY J. W. SCOTT MACFIE, M.A. CANTAB., M.B., CH.B. EDIN.;
AND
J. E. L. JOHNSTON, M.B., B.S. LOND., D.T.M. & H. CANTAB.

(*From the Medical Research Institute, Lagos.*)

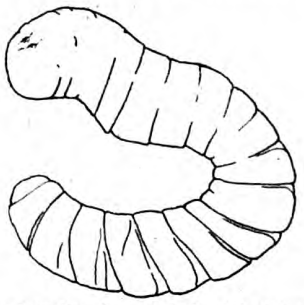
UP to the time when Sambon published his important paper on Porocephaliasis in Man[1] apparently but few cases had been recorded. In a subsequent paper[2] the same author added to his list four other records. It has, however, been pointed out by Löhlein[3] that the infrequency of the occurrence of this condition which might be deduced from the small number of cases on record does not really exist. He records how Seiffert found porocephali in 7·8 per cent. of necropsies performed on coloured railway workers in the Cameroons, and how he himself, in a series of 118 post-mortem examinations on negroes, found 10 infected with these larvæ. Borden and Rodhain have recorded cases from the Congo also, so that it would appear that porocephaliasis is not very uncommon in the natives of West Africa.

The five cases briefly described below occurred in Southern Nigeria. The first occurred at Ibadan, a large native town situated about 120 miles north of Lagos, the second at Calabar, the third at Itu, and the fourth and fifth at Degama. We are indebted to Dr. J. D. Finlay for the interesting account of the first case, to Dr. J. Currie for the notes on the second, and to Dr. A. H. Wilson for the records of the remaining three.

CASE 1.—The patient was a native man, aged about 24, who was brought to the Ibadan Hospital on July 31st, 1913. He died immediately after his admission, and in consequence the history of his case is somewhat vague. He is said, however, to have been taken ill five days previously, and the symptoms observed were fever and vomiting. At the post-mortem examination, performed by Dr. Finlay, the body was found to be well nourished, rigor mortis was present, and the conjunctivæ were noticed to be deeply stained. All the organs and tissues were intensely jaundiced. Lungs: The right lung was normal; the left lung was contracted, and the pleural cavity was filled with venous blood and dark clot. Heart: The cardiac muscle was soft. No valvular lesion was present. Liver: The liver was greatly enlarged, bile-stained, and somewhat soft. On its surface, just below the peritoneal covering, were several porocephalus larvæ, and in the substance of the organ a few more were found. There were also some lying free on the under surface of the liver. The gall-bladder was filled with thick bile. On section the liver showed the condition known as "fatty nutmeg liver." Stomach: The stomach was contracted and thickened, and Dr. Finlay compared its appearance to that of an ox. Several round worms were present in the cavity. Duodenum: The duodenum was surrounded by a hard mass which blocked the common bile-duct. On microscopical examination this mass appeared to be of the nature of an adenocarcinoma. Intestines: The small intestine appeared to be normal, but the ascending colon was adherent to the hard mass referred to above. Kidneys: The kidneys were enlarged and stained a dark green colour. The larvæ on examination proved to be those of porocephalus armillatus. Three individuals measured 18 mm., 16 mm., and 15 mm. in length, and comprised 21, 19, and 17 rings respectively. The rings in the middle of the body were 1 mm. apart, and stood out prominently. The breadth of all three was 3 mm. The cephalo-thorax appeared to be identical with that figured by Sambon for this species.

CASE 2.—The second case was that of an old Hausa woman who was found dead by the police at Calabar in September, 1913. Dr. Currie, who was called upon to make a necropsy, determined that death had been due to extensive and long-standing dysentery. In the course of his examination he found a single larva of porocephalus armillatus encysted in the edge of the liver. No more of the parasites were found in other situations.

CASE 3.—The patient, whose age was about 40, was a native of Southern Nigeria, and an inmate of Itu prison. He was a big, well-developed man. who did not appear to be seriously ill. Only a very indefinite account of his illness could be obtained. He first complained of being sick on August 5th, 1910, stating that he was constipated and had vague pains about the abdomen. At the same time he noticed that his legs began to swell. He was first seen by Dr. Wilson on August 11th, and was found to have œdema of his legs, scrotum, and abdominal walls. The abdomen was distended, and contained free fluid. There was no enlargement of the liver and spleen, the urine was normal, and the heart and lungs appeared to be healthy. He was not very weak, and could get about fairly well. The patient was removed to Ikot Ekpene. On August 15th, when he was next seen, there was an increase of the dropsy; dyspnœa was present, with a cough and frothy expectoration. On examination of the lungs moist crepitations were



[1] Journal of Tropical Medicine and Hygiene, July 15th, 1910.

[3] Beiheft zu Archiv für Schiffs- und Tropen-Hygiene, 1912, vol. xvi., No. 9.

heard, and there was slight impairment of the resonance, especially on the right side. The patient died on August 18th. A post-mortem examination was made four hours after death. The body was well nourished. There was œdema of the legs and scrotum and slight general anasarca. On opening the abdomen a large amount of clear ascitic fluid escaped. There was no sign of peritonitis. The spleen was normal in size and appearance. The kidneys seemed to be a little congested. The liver was slightly enlarged, but in general appearance looked healthy. Scattered over its surface and in each lobe were what looked at first glance like cicatricial patches, but these proved on closer examination to be the encysted larvæ of porocephalus armillatus. Altogether there were 10 or 12 to be seen. They were all situated superficially, and were of a whitish colour. They were about half an inch long, closely coiled up, and surrounded by a thin membrane. Exactly similar larvæ were found in the lungs, but they were not so numerous as in the liver, and one of them lay an inch from the surface. The lungs were generally congested, and contained much frothy fluid. The bronchial tubes showed signs of congestion. There was no increase of fluid in the pleural cavities, a few slight adhesions were present, but there were no signs of recent pleurisy. The heart was normal. The pericardium contained an excess of fluid. The intestines were normal in appearance, and no larvæ were seen on their surfaces. The mesentery and the glands were not especially examined.

CASE 4.—The patient, a male native, aged about 50, was a prisoner from the Ahoada district of Southern Nigeria. In April, 1913, he was admitted to hospital at Degama for observation, but his symptoms appear to have been somewhat vague and indefinite, and in the same month he was transferred to Bonny. In August he was re-transferred to Degama. On re-admission it was noted that he was in "an emaciated and generally feeble condition," but no definite disease was diagnosed to account for his condition. His asthenia was progressive, and he could only walk feebly for a few yards at a time. He was discharged on Sept. 5th, but remained in the prison awaiting transport to his own country. About the same date it was observed that his abdomen was somewhat swollen, and on examination the presence of free fluid was detected. Two days later the feet and legs became œdematous, and asthenia became extreme. On the 11th dyspnœa and cough supervened, and the lungs were found to be congested. There was no fever and the urine was normal. Two days later the patient died. At the post-mortem examination, which was made by Dr. Wilson on the same day, the body was found to be emaciated and the legs slightly œdematous. Thorax: The heart appeared to be normal. There were a few old adhesions on both sides in the pleural cavities. Both lungs were much congested, and on the surfaces ecchymoses were found. On section a large amount of blood and frothy fluid escaped, the condition being one of general congestion and œdema. The lungs were searched for larvæ, but none was found. Abdomen: On opening the abdomen a large amount of limpid fluid escaped. There was no peritonitis. The liver was normal in colour and appeared to be below the usual size, and was tough in consistency. On its surface was a number of cicatricial patches. On further examination a nodule about ¼ inch in diameter was found on the surface of the right lobe. This proved to be an encysted larva enclosed in a very tough and fibrous capsule. On thoroughly searching the liver four similar encysted larvæ were found. The mesentery was searched for larvæ, but with negative result. The spleen, kidneys, pancreas, and stomach and intestines were all normal.

CASE 5.—The patient, a Kroo boy, aged about 17 years, was admitted to Degama Hospital on July 7th with ulceration of the cornea of the right eye. He made no further complaint, and the examination of his physical condition was negative. He was, however, reported to have been losing strength recently and to have been performing his work in a languid fashion. Whilst in hospital his condition was one of gradual and progressive asthenia, and he died on July 14th. Two weeks before his death his gait became staggering, his knee reflex was lost, and he complained of some vague pains about the legs; but with the exception of rapid action of his heart no local signs or symptoms could be detected, and no evidence of cardiac incompetency was found. At the post-mortem examination the body was found to be fairly well nourished and presented no abnormal appearances. Thorax: The pericardium was adherent to the heart, the right ventricle thin and dilated, the left ventricle normal, and the valves normal. The lungs were very small but appeared to be healthy; no porocephalus larvæ were found although careful search was made for them. Old pleuritic adhesions were present on both sides. Abdomen: The abdominal cavity contained a little free peritoneal fluid, but there were no signs of peritonitis. The liver was slightly enlarged, there was general hepatitis, and the organ presented a nutmeg appearance. On the surface two patches with a superficial resemblance to cicatrices were found, which when cut into were seen to be encysted larvæ of porocephalus. On making successive sections through the liver about ten of these larvæ were found. None was more than a half to three-quarters of an inch beneath the surface. One larva was found in the mesentery. The kidneys, pancreas, stomach, and intestines were all normal.

The parasites from the last case had unfortunately been considerably damaged in dissection, and only one complete individual could be pieced together. This specimen (see figure) consisted of 20 rings, and

Porocephalus from Case 5, magnified. Actual length, 17 mm.

measured 17 mm. in length and 3 mm. in breadth. An unopened cyst from the same case measured 9 mm. by 6 mm. by 3 mm. The larvæ differed somewhat from those of the other cases. They were smaller, and the rings, which were broad and band-like, were set more closely together. The heads also appeared to be more bulbous. Such differences in appearance may have been due to the larvæ having been in an immature condition.

Very various opinions are held with regard to the effects of porocephalus larvæ on their human host. Löhlein seems to believe that they are harmless, but Chalmers states: "The presence of the parasite in the human body sets up inflammation of the lungs and peritoneum, but it does not appear to irritate the alimentary canal or liver."

In the first two cases recorded above sufficient evidence of disease was detected at the necropsies to account for death without attributing any action to the presence of the larvæ. In the second case only a single porocephalus larva was found in the body, but there was evidence of severe and chronic dysentery, and in the first death would appear to have been due to the presence of a tumour surrounding the duodenum and blocking the common bile duct, and the few symptoms noted, and the pathological appearances observed, were probably due to this cause. The possibility that irritation caused by wandering larvæ might have played some part in the production of the tumour should not, however, be forgotten, although no evidence of any such predisposing cause was detected at the necropsy. The three cases recorded by Dr. Wilson (Nos. 3, 4, and 5), on the other hand, suggest that the presence of porocephalus larvæ may have serious pathological

significance. No definite cause of death was discovered at the post-mortem examinations, and Dr. Wilson himself considered that the fatal termination in each case had at any rate been accelerated by the presence of the larvæ. These three cases presented a peculiar clinical picture, and the pathological conditions found after death were somewhat similar. The chief symptoms were progressive weakness, œdema, and dyspnœa, without any very definite signs to account for the physical conditions. The patient in Case 5 developed some interesting nervous symptoms shortly before death. A larva was found in the mesentery, a fact which suggests the possibility that wandering larvæ may have been responsible for some of the symptoms. It is interesting to note that Waldow found small cysts containing calcified porocephali in the liver, omentum, mesentery, and pleura of a native who died in the Cameroons with symptoms of meningitis.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE RESULT OF CEREBRAL DECOMPRESSION IN A CASE OF EPILEPSY.

BY ALLAN WATSON, M.B., CH.B., D.P.H., D.T.M. & HY. EDIN.

THE results of surgical treatment in cases of idiopathic epilepsy have been, on the whole, so discouraging that the following notes on a case which was markedly benefited by Kocher's decompression operation may be of interest.

The patient, a boy aged 16 years, was sent to the East Suffolk Hospital from the Ipswich Mental Hospital on Sept. 26th, 1912. He suffered from frequent epileptic fits, and was certified as being a person of unsound mind. He was an illegitimate child, and was born prematurely at about the end of the eighth month. At the time of his birth his father was 20 and his mother 19 years of age. When the patient was about 3 months old he suffered from severe "convulsions," but he was otherwise healthy until he was in his eleventh year. He is said to have had a fall on his head when about 5 years of age, but he was not unconscious after the accident, and was apparently none the worse for it. He commenced having epileptic fits when he was 10½ years old, and shortly afterwards some paresis of the right hand and arm was observed. The fits at first recurred about once every two days. When he was about 11 years old he injured his left eye and had to have it enucleated. Towards the end of November, 1911, the fits became much more severe and increased greatly in frequency, recurring 10 or 12 times a day. About this time also he began to show signs of insanity. He was admitted to the Ipswich Mental Hospital on Dec. 4th, 1911, showing the following signs of insanity, as stated on his certificate: "He talked of committing suicide and had asked for a rope and a razor to do so. He had fits of unprovoked laughter, and at times talked incoherently. He had no recollection of dates. He had occasional fits of violence and excitement." While he was an inmate of the Mental Hospital he had an average of about 10 fits daily.

Neither of the patient's parents suffered from epilepsy, insanity, alcoholism, syphilis, or tuberculosis. A maternal uncle suffered from general paralysis of the insane, and a paternal uncle suffered from melancholia. His father also had had a great-uncle who was insane for many years.

The patient was a fairly well-developed, intelligent-looking lad. His features were small and his forehead was narrow. His complexion was fair. There were no marks of injuries about the head, but the skull was distinctly flattened over the left parietal region. The following cranial measurements were noted: (1) Circumference taken just above level of superciliary ridges, 21¾ inches; (2) distance from nasion to inion across top of skull, 15 inches; (3) distance from right to left suprameatal points across top of skull, 12 inches. The colour of the right eye was blue. The pupil was of medium size and reacted sluggishly to light and accommodation. The knee-jerks were present and were fairly active. He seldom used his right hand and arm, which were less well developed than the left. The right elbow- and wrist-joints were usually held flexed, but he could extend both voluntarily. He answered questions promptly as a rule, but in a rather listless manner. His memory was fairly good for recent events, but not good for remote events. At times he was rather incoherent. He took very little interest in his surroundings. There was no evidence of congenital syphilis or of tuberculosis.

The patient was kept under observation for a week after his admission to hospital. He had daily from 12 to 15 fits of varying severity. There was never an aura of any description. Occasionally the fits commenced with a cry which was sometimes a yell, but more often a loud groan. The tonic spasm nearly always seemed to commence in both arms simultaneously; it usually, but not invariably, became general. The eye generally turned inwards and upwards, but sometimes outwards and upwards. The clonic spasm usually began on the right side of the body, but the muscles first affected varied; occasionally it began on the left side, and on a few occasions both sides seemed to be affected simultaneously. The clonic spasm usually became general. He was invariably unconscious during the fits for several seconds at least. Occasionally he was unconscious for a few minutes after a fit, but more generally he was conscious, though dazed and unable to speak for a little. He frequently passed urine or fæces involuntarily during or immediately after the fits.

An operation was performed on Oct. 4th, 1912. The patient was trephined over the left Rolandic area, and the opening was enlarged with gouge forceps until it measured about 3 by 2 inches. The dura mater was reflected, but no abnormality was noted save slight flattening of the cerebral convolutions. The brain surface was covered with Cargile membrane and the wound was closed in the usual manner. The patient remained unconscious for about 15 hours after the operation. When he recovered consciousness it was noticed that his right arm and leg were paralysed. On Oct. 7th he had one rather severe fit. The tonic spasm began in the right arm; the clonic spasm was general. Some hours later it was noted that he could move his right arm and leg voluntarily. By the 12th he had regained complete control over both limbs. He could use his right arm very much better than he could before the operation, and it was no longer held with the wrist- and elbow-joints flexed. His mental condition improved very rapidly and remarkably; he became bright and cheerful, and took an intelligent interest in everything. He had one very slight fit on the 23rd and another on the 24th. On

Nov. 5th he was discharged. He was apparently quite sane and the paresis of the right arm had completely disappeared.

A report on the patient received six months after the operation stated that he had had 12 slight fits since his discharge from hospital, but was quite sane and in excellent health.

I am indebted to Dr. Herbert H. Brown, honorary surgeon to the East Suffolk Hospital, for permission to publish the notes on the case.

Evanton, N.B.

TORSION OF THE PEDICLE OF AN OVARIAN CYST ON EACH SIDE,

WITH ADHESION OF AN INFLAMED APPENDIX VERMIFORMIS TO THE CYST ON THE LEFT SIDE.

BY CECIL MEREDYTH-JONES, M.B., B.S. LOND.,
HOUSE SURGEON AT WESTMINSTER HOSPITAL.

A WOMAN, aged 50, was admitted to Westminster Hospital on Dec. 30th, 1912, under the care of Mr. W. G. Spencer, complaining of violent pain in the abdomen most marked in the *right* iliac fossa and hypogastrium. She had noted the abdomen gradually enlarging for more than a year, and at times had felt "vague movements," but had not consulted a medical man. Her menstrual periods had become irregular for two years, but she had had some blood-stained discharges at intervals of from three to six months. She had first felt pain after a slight strain some two months before; pain had recurred at intervals, but was relieved by lying down. The acute attack of pain commenced on Dec. 27th, since when she had had no motion, and felt nausea but had not vomited.

On admission the patient was in distress with pain and great thirst. She had a dry, furred tongue, the pulse-rate was 130, and the temperature was 99·6° F. The abdomen was not markedly distended; there were no coils of intestines to be seen. A lobulated mass could be felt in the hypogastrium extending towards the *right* iliac region, which was tense and could be swayed a little, but it did not fluctuate; except over this the abdomen was resonant to percussion. Per rectum the pelvis could be felt to be occupied by a semi-fluctuating mass which pitted on pressure; the uterus was pushed forwards and downwards.

Mr. Spencer diagnosed an ovarian cyst with a twisted pedicle; the collection in the pelvis was supposed to be peritoneal fluid shut off from above by adhesions. A Pfannenstiel's incision—i.e., a curved incision through the skin and anterior sheath of the recti with a separation and retraction of the muscles—was made midway between the umbilicus and pubes. The bladder presented in the wound, for although it had been emptied it had been drawn up by the ovarian cyst, to which it had previously become adherent; also some intestinal adhesions were separated. Then a cyst of the size of a large cocoa-nut was found which had arisen from the *left* ovary, but its pedicle having undergone axial rotation the cyst had come to occupy the *right* of the hypogastrium and *right* iliac fossa, while the uterus had been rotated, so that its *left* cornu looked backwards and its *right* forwards. To this cyst the appendix was densely adherent, the appendix itself being excessively long, thickened, and kinked. It was removed and the stump buried in the cæcum. Then the cyst was brought out; it was blue from venous congestion but not yet gangrenous; its long pedicle had been twisted through about a circle, and its blood-vessels were thrombosed. On further examination after removal the cyst proved to be a multilocular ovarian cyst, some of the cysts containing putty-like remains of blood-clot. After drawing up the uterus and separating more adhesions the mass in the pelvis was found to be the remains of a right-sided multilocular ovarian cyst, the pedicle of which had become twisted, the cyst wall gangrenous and ruptured, but the contents had been confined to the pelvis by the adhesions above. After removing it the pelvis and rest of the lower part of the abdomen were sponged dry, a glass tube was passed into the pelvis, and the abdominal wall sutured in layers around it. The patient made an uninterrupted recovery and was able to leave for a convalescent home within a month.

The patient appears to have developed a multilocular cyst from each ovary about the size of a large cocoa-nut. During this time an exceedingly long appendix became kinked and inflamed, which led to adhesions to the cyst on the *left* side, to slow twisting of the pedicle, with the formation of adhesions to the bladder and intestines. The slow development of this condition, with the twisting of the fundus of the uterus, led to the cyst on the *right* side being crammed down into the pelvis, in the course of which its pedicle became twisted, the sac wall gangrenous, and rupture followed. It would appear that the acute symptoms were produced by the rupture of the *right* ovarian cyst in the pelvis. The complicated nature of the case had to be unravelled in the course of the operation.

I am indebted to Mr. Spencer for permission to publish the notes of the above case.

Westminster Hospital.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Pyelo-Radiography.

A MEETING of this section was held on Nov. 11th, Mr. G. H. MAKINS, the President, being in the chair.

A discussion took place on Mr. F. S. KIDD'S paper published in THE LANCET of Oct. 25th.

Mr. S. G. SCOTT spoke of the details of the radiographic examination in such cases. He said that the couch should be raised on wooden supports, as the usual couch used in radiography was not high enough. The surface should be of polished wood with a loose covering of thick felt, so that the patient could be slipped freely along it without muscular effort on his part. At the time of the examination he should be slipped to the foot of the couch, his legs raised and thighs supported. A suitable catheter was one which was divided into sections, opaque areas of one inch alternating with transparent areas of a quarter of an inch. After the collargol had been injected the patient should be put back into his original position, and the plate so arranged that the last rib occupied its centre. Each kidney should be skiagraphed separately. Compression from above aided the examination. The pelvis of the kidney should be kept full during the exposure, and the tube through which the collargol

ran should not be clamped, because this led to leakage round the catheter. The exposure occupied from 15–20 seconds, and then the collargol should immediately be run out. He did not think it advisable to watch the pelvis filling by the fluorescent screen. The whole process should last a few minutes only.

Mr. J. W. THOMSON WALKER said that the procedure required the coöperation of the surgeon with the radiographer. The patient should remain in bed for a day or two afterwards. It could not be denied that there was a certain element of danger, so that it should not be employed except in those cases where the information which it gave was important enough to justify its use. One class of case to which it was applicable was where hydronephrosis was diagnosed, and by pyelography none was seen. In this way an operation was avoided. In another class were cases where renal symptoms were present, but the kidney was not palpable. A third consisted of cases of renal tumour, and a fourth those in which radiography showed a shadow of doubtful origin, and in which by pyelography the relation of the calyces of the kidney to the shadow was made clear. One case had been described where the renal pelvis had been ruptured. It was not justifiable to use force in introducing the fluid, and the inflow should be stopped if pain was induced. This, however, was not always a reliable guide. No anæsthetic should be employed. If the fluid did not run in with a continuous flow another warning of danger was afforded. He had lately used solutions of from 10 to 15 per cent., or even 20 per cent., to ensure a good shadow. In one case he had found œdema of the fat around the kidney, which he ascribed to this method of examination.

Mr. A. RALPH THOMPSON said that he had found great assistance from pyelography in the planning of operations upon kidneys, especially when they were out of place, and also in determining the relation of the kidney to surrounding structures. He thought that a knowledge of X ray anatomy was important, and should if possible be standardised.

Mr. A. E. JOHNSON had found the method of use in cases of unilateral renal pain of unknown origin, in doubtful cases of hydronephrosis and pyonephrosis, in congenital defects of the urinary system, in abdominal tumours, and in the interpretation of X ray shadows. It was of great value in demonstrating early dilatation of the pelvis. He recommended that the tip of the catheter should be identified by the screen before running in collargol, and advised against compression from above. In his opinion the dorsal position was the best. In movable kidneys he had sometimes obtained advantage by examination of the patient in the standing posture.

Mr. KIDD replied.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Oct. 24th, Dr. LEONARD G. GUTHRIE, the President, being in the chair.

Dr. C. E. ZUNDEL showed two cases of Infantilism.

CASE 1.—The patient was a girl, aged 13 years, the eldest of three children, the others being healthy. She was very small at birth, and "does not seem to have grown since she was five years old." The patient was 3 ft. 6 in. in height, and her weight was 2 st. 10½ lb. The face was intelligent; the skin was dry; the hair was fair and rather coarse. There was no suggestion of appearance of puberty. Urine: Acid, pale, specific gravity 1004, contained 1/20 albumin, and a few granular and fatty casts were found in the centrifuged specimen. No polydipsia; occasional nocturnal enuresis.

CASE 2.—The patient was a boy aged 13 years. Since the age of 2½ years he had had polydipsia. No other illness before or since, but his excessive thirst had been constant. His father and one brother had also suffered from diabetes insipidus. Condition: Thin, childish, weight 2 st. 1½ lb., height 3 ft. 6 in.; thymus, thyroid, and pituitary gland apparently normal. Drank on the average 14 pints per diem. Disliked sweet things; appetite poor. Urine: Specific gravity 1001, no albumin, no casts, urea 0·5 per cent. Wassermann reaction negative.

Dr. E. A. COCKAYNE showed a case of Constriction of the Arm by Amniotic Bands.

The patient, a girl aged 3½ years, showed a narrow fibrous band completely encircling the right upper arm, causing slight constriction, and another which deeply constricted the forearm just above the wrist; in flexion—the intrauterine position—the two scars were at the same level. The scar tissue was adherent to the deeper structures and the bone felt grooved, but a skiagram showed that it was not involved. The right arm and hand were well developed and larger than the left, showing that there had been no pressure on the arteries.

Dr. COCKAYNE also showed a girl, aged 1 year and 4 months, with Hemiplegia and a very extensive Nævus.

The birth was easy, but the child was said to have been "born in convulsions." The mother attributed the condition to her having seen a cripple with a very large birthmark when she was three months pregnant. The mother noticed the nævus at birth, but was not sure whether the hemiplegia was present then or came on later. It was first noticed after the child had had a severe left-sided fit at the age of six weeks. She had had similar fits at intervals up to the age of one year. There was complete left hemiplegia with spasticity of the arm and leg, and the left side, including the face, was noticeably smaller than the right. There was very extensive port-wine staining of the skin of the scalp, face, arms, legs, and part of the trunk. It was fairly symmetrical and followed a posterior root distribution. Wassermann's reaction negative.

Dr. J. PORTER PARKINSON showed a boy, aged 5 years, with Rheumatoid Arthritis.

In July, on admission to hospital, the patient was pale and thin, with wasted muscles. The knees, ankles, wrists, and elbows were swollen and spindle-shaped, with soft, pulpy swelling. Enlarged glands could be felt in the axillæ and groins, but the spleen could not be felt and showed no evidence of enlargement. Teeth good; no evidence of gastro-intestinal derangement. Weight 2 st. 1 lb. Wassermann and von Pirquet's reactions normal. Temperature occasionally up to 100° F. Treatment consisted of massage, &c., a course of arsenic internally, and, later, rectal injections of polyvalent antistreptococcus serum, but without effect. The patient left the hospital at the end of July, and on readmission in October, in addition to the conditions described above, there were spindle-shaped enlargements of all the joints of the fingers and slightly of the metacarpophalangeal joints of both hands, and the left hip-joint had become fixed in partial flexion.

Dr. T. R. WHIPHAM showed three cases of Underdevelopment.

CASE 1.—A rickety boy, aged 2 years and 3 months, who was very undersized, being only 2 ft. high and weighing only 11 lb. The anterior fontanelle was open and the patient had only seven teeth.

CASE 2.—A boy, aged 8 years, of diminutive stature, but well proportioned and intellectually bright. Height 2 ft. 9 in.; weight 1 st. 8½ lb. No signs of rickets, but the patient suffered from tuberculosis of the skin and subcutaneous tissues. He had been treated with thyroid extract and more recently with polyglandin, with some improvement.

CASE 3.—A girl, aged 18 years, showing signs of hyperthyroidism. She had the development of a girl aged 10, her

height being 4 ft. 1½ in. and her weight 4 st. 10½ lb. There was an absence of mammary development, also of both pubic and axillary hair, and menstruation had not occurred. The girl had attended school, but was not quite up to the normal standard and her memory was not good.

Dr. WHIPHAM also showed a girl aged 6 years with Enlargement of the Liver and Spleen associated with Jaundice.

The patient was born jaundiced, the colour being "green-yellow," and the condition lasted for six weeks. Since then no jaundice had been noticed until February of this year. The onset was sudden, and when the patient was first seen in May she was deeply jaundiced, being of an olive-green colour all over. The liver was greatly enlarged, extending to the umbilicus, and the spleen was also of considerable size, extending down to the same level. The blood count at this time showed red corpuscles, 4,824,000 per c.mm.; white cells, 15,200 per c.mm.; polymorphonuclears, 39 per cent.; lymphocytes, small, 53 per cent.; lymphocytes, large, 6 per cent.; and eosinophiles, 2 per cent. No myelocytes or mast cells were seen. The motions were brown or yellow in colour, not acholic, but the urine was deeply coloured and contained bile-pigment. Wassermann reaction negative. After persisting for three months the jaundice had been gradually getting less during the last two months. The liver edge was now 1½ in. above the umbilicus, but the spleen had slightly increased in size. A recent count showed a change in the blood picture: Red corpuscles, 2,360,000 per c.mm.; white cells, 38,000 per c.mm.; polymorphonuclears, 50 per cent.; lymphocytes, small, 28 per cent.; lymphocytes, large, 4·7 per cent.; myelocytes, 13·3 per cent.; eosinophiles, 3·7 per cent; and mast cells, 2·2 per cent. Nucleated red corpuscles were present and a few of the myelocytes contained eosinophile granules. Hydropic degeneration of the nucleus was frequent, especially in the myelocytes and the large lymphocytes. The urine was still pigmented and contained bilirubin, but no urobilin.

Dr. LEONARD GUTHRIE showed a case of Congenital Insufficiency of Ocular and Facial Movements in a boy aged 4 years.

At birth imperfect closure of the eyes was noticed and also that the face was devoid of expression. The whole face was motionless as far as the mouth; the skin of the face was smooth and not tightly stretched. The eyes could not be completely closed, the eyeballs were in mid-position, and the only ocular movement was convergence downwards and inwards. The pupils were equal and reacted to light, less so to accommodation. Laughter was only represented by guttural grunts. The orbicularis oris was not paralysed, this being probably due to association of its action with that of the tongue. Electrical reactions could not be obtained in any of the facial muscles except the orbicularis oris. The condition was regarded as an unusual form of myopathy affecting muscles supplied by the third and the seventh nerves.

Dr. F. LANGMEAD showed a case of Cretinism.

The appearance of the patient, a female child aged 5 months, was characteristic. The child was shown because she exhibited two features which are characteristic of Mongolian imbecility rather than of cretinism—(1) markedly incurved little fingers and (2) congenital morbus cordis.

Dr. E. BELLINGHAM SMITH showed a case of (?) Cerebellar Encephalitis.

The patient a boy aged 8 years, was admitted as a case of cerebro-spinal meningitis. On July 25th there had been a sudden onset, with headache, vomiting, and aching pains. On admission on the 26th the boy was drowsy, with flushed face, rigidity of the neck muscles, and some retraction of the head. The abdomen was retracted, the reflexes were exaggerated, the plantar reflexes extensor, and Kernig's sign and ankle clonus were well marked. Temperature, 103° F. Lumbar puncture revealed a turbid fluid, not under pressure, containing 0·075 per cent. albumin; globulin a small precipitate, glucose present, also many polynuclear cells and large lymphocytes. No organisms seen; cultures sterile. On August 8th commencing optic neuritis was noticed which became more marked. On Sept. 4th fluid from a second lumbar puncture was also sterile. 9th: No paresis of the limbs but well-marked ataxia, the incoördination being equally present on both sides. 15th: The patient was put on iodide of potassium, since when symptoms have rapidly cleared up and the child seems now practically well.

Dr. BELLINGHAM SMITH also showed a case of Infantile Paralysis of early onset and with unusual deformities.

The disease came on when the child was only two months old. The patient was quite unable to sit up and usually lay with both knees flexed and the hips abducted so that the thighs were at right angles to the pelvis. The left leg could be readily brought down into a direct line with the trunk, but the right was incapable of complete inward rotation and adduction.

Dr. PORTER PARKINSON showed a specimen of Neoplasmoid of the Sigmoid Flexure from a boy aged 5 years.

When admitted to hospital on July 17th there was a distinct, rounded, movable, tender lump of the size of an orange in the right iliac fossa. On Sept. 29th, after several motions containing large quantities of blood, the child died. At the necropsy the lump was found to be a distended sigmoid colon lying in the right iliac fossa and adherent to the adjacent small intestine. The walls of the sigmoid were much thickened with hard, whitish growth, the inner surface being ulcerated. A microscopical section showed somewhat large, rounded, and tailed cells packed in the meshes of fibrous tissue alveoli.

In the opinion of Dr. Porter Parkinson and of others the growth was a carcinoma.

Dr. J. D. ROLLESTON showed a specimen of Extensive Diphtheria of Trachea and Bronchi from a girl aged 5 years.

The specimen showed membrane closely adherent to the posterior surface of the epiglottis and interior of the larynx, from the lower end of which a thick continuous tubular cast extended to the bifurcation of the trachea and passed into each of the bronchi.

Dr. F. G. CROOKSHANK showed a skiagram of a case of Anomalous Development.

The lower limbs were small, immobile, and presented webbing between the thigh and the calf. At the post-mortem examination it was found that the spinal column terminated at the twelfth dorsal vertebra in a bony mass of small size. The spinal canal was completely closed. There were 12 pairs of dorsal nerves, but no lumbar nerves at all, and the legs were seemingly not innervated. A very rudimentary sacrum and coccyx were present. For several months before and after the date of the child's conception the mother had been in close daily association with a little boy, paralysed as the result of Pott's disease, who died when the mother was four months pregnant.

Mr. DUNCAN C. LL. FITZWILLIAMS showed a specimen of Extrapleural Lipoma from a child aged 6 years.

The case had been shown at the meeting of the Section in January as a case of lymphangioma, resembling hernia of the lung. The swelling gradually became larger, and in September the lump was exposed and removed. It proved to be a pure lipoma with very little fibrous tissue. The portion in the neck communicated by a narrow isthmus growing down behind the subclavian artery with a much larger portion which lay within the thorax outside the parietal pleura. The tumour, which was very soft, was removed whole.

SECTION OF OPHTHALMOLOGY.

Exhibition of Cases.—The late Mr. E. Nettleship.—Disease in the Eyes of Animals.—Obstruction of the Lacrymal Duct and its Treatment.

A MEETING of this section was held on Nov. 5th, Sir ANDERSON CRITCHETT, the President, being in the chair.

Mr. SYDNEY STEPHENSON showed a case of Brawny Scleritis at an early stage, which Mr. E. TREACHER COLLINS thought was a tenonitis. He had had a

case of this condition which persisted for a long time, as had this one.—Mr. W. T. HOLMES SPICER reminded the meeting of a case with a similar appearance which he showed at a former meeting under the title "solid œdema of the conjunctiva." That, however, had a syphilitic origin, which apparently was not the case here.—Dr. D. LEIGHTON DAVIES spoke of a case under his care with a similar appearance. A small portion examined showed round cells without a stroma. He enucleated, and on bisecting the globe found a darkly pigmented sarcoma. He suggested that the present case was sarcoma.

Mr. J. L. BARLEY showed a case of Keratitis Punctata.

Mr. C. KILLICK exhibited a case of Persistent Hyaloid Artery.

Dr. A. S. COBBLEDICK showed an example of Ectasia of the Cornea four years after a perforating wound; also a case of Rupture of the Choroid in a Myope following Labour. The latter case he regarded as unique.

Mr. N. BISHOP HARMAN showed a patient with New Growth causing detachment.

Mr. GEORGE COATS exhibited a Dog with Keratitis.

Mr. E. CHATTERTON showed a case of Tuberculous Iritis in order to elicit opinions as to the value of tuberculin injections for the condition.—Mr. S. H. BROWNING said he had treated a number of such cases with tuberculin, and he knew of no case in which hæmorrhage had followed its use. The French believed the hæmorrhages which occurred were of tuberculous origin.—Mr. M. S. MAYOU stated that he had treated numerous cases of tuberculous iritis with tuberculin, and had not seen hæmorrhages during the treatment; there was absorption of the nodules, and subsidence of the iritis. It was the most successful treatment. He commenced with 1/10,000th, and worked up to 1/250th mgm. T.R. Where there was lung trouble also, a very small dose caused severe reaction, and it should be given very cautiously.—Mr. A. MACNAB said he had recently treated two cases in this way, and both did very well.—Mr. ARNOLD LAWSON gave confirmatory experience.

Mr. J. HERBERT PARSONS showed a Central Unilateral Retinitis.

Dr. A. HUGH THOMPSON exhibited a case of Choroiditis starting as a ring round the macula.

The PRESIDENT made sympathetic reference to the death of Mr. Edward Nettleship, which was a loss not only to the society but to the world of ophthalmology. Though evidently in failing health, his mental vigour was such that he took part in the discussions at the recent Congress of Medicine. The speaker's father and Mr. Bowman had the highest opinion of Mr. Nettleship's pathological knowledge in the early days, and that opinion had been amply justified since. A resolution of condolence with his relatives was carried by members upstanding.

Mr. G. COATS read a paper in which he reported some examples of Disease in the Animal Eye. He described a form of keratitis characterised by the presence of a superficial vascular opacity of the cornea. The disease was of long duration and had no evident association with distemper or other general illness. It sometimes occurred in more than one member of the same litter. Pathologically, it consisted in a replacement of the superficial layers of the cornea by a layer of inflammatory tissue. The human condition which it most nearly resembled was trachomatous pannus, but it differed from that disease in the absence of follicles, and of scarring or distortion of the lid, as well as by its not being confined to the upper part of the cornea. A case of retinal degeneration following distemper was described. The retinal changes were peculiar in that it was the bipolar cells of the inner nuclear layer which were chiefly affected, the ganglion cells showing only slight, and probably secondary, changes, the outer layers being mostly intact. In places, however, the rods and cones and their nuclei were also atrophied. These changes were probably to be explained by the presence of a circulating toxin with a specific affinity for the retinal bipolar cells, analogous to the specific action of nicotine on the ganglion cells. A description of some cases of choroido-retinal degeneration and inflammation was prefaced by a discussion of the pathological points of distinction between these two conditions. A profound atrophy of the retina without adhesion to the choroid must be a degeneration. In old-standing cases of degeneration, however, an adhesion between the two membranes occurred, but it was usually not very intimate; the line of demarcation remained well defined, and the elastic lamina of the choroid was intact. The occurrence of cicatricial tissue was certain proof of precedent inflammation, and where it was present the adhesion was dense and the layers of the choroid and retina were distorted and disorganised, instead of being merely atrophic. A degeneration was often fairly uniform over a considerable area; an inflammation was patchy. Examples of choroidal-retinal degeneration in a dog, racoon, wolf, wild sheep, ferret, wallaby, and hyæna were shown. The racoon appeared to be an albino, yet a little pigment was present in the epithelium of the ciliary body and anterior part of the choroid, showing that pure albinism could not be diagnosed without a microscopical examination. The racoon also showed nystagmus—a condition occasionally described in the lower animals. A case of choroiditis, cyclitis, and keratitis in a bear, and one of anterior choroiditis in a peccary were also illustrated. Two instances of canine irido-cyclitis were reported. The first was of plastic type, and was peculiar only in its occurrence in the dog, in which animal the condition appeared to be rare; the second, also in a dog, was characterised by an enormous thickening of the iris, due to infiltration with mononuclear cells of a special type. Posterior synechiæ and other features of plastic iritis were absent. The cause of the irido-cyclitis was obscure in both instances.—The paper was discussed by Mr. TREACHER COLLINS, Mr. J. B. LAWFORD, Mr. SEWELL (veterinary surgeon), Dr. RAYNER D. BATTEN, Mr. BISHOP HARMAN, Mr. HOLMES SPICER, Mr. W. LANG, Mr. R. R. CRUISE, and the PRESIDENT, and Mr. COATS replied.

Mr. CHARLES WRAY read a paper on Obstruction of the Lacrymal Duct and its Treatment. He believed it was a mistake to remove the sac when syringing failed without attempting to cure by means of styles, or styles and probing combined, and thought it was not unlikely that ectropion and its sequelæ might follow excision. Too much was heard of the satisfactory and immediate results, but too little of bad ones and of recurrences. After referring to the danger of adrenalin and chloroform when used at the same time, stress was laid on Harrison Butler's operation. According to the speaker, all cases of epiphora should be rhinoscoped, though he admitted he had received little or no help from the rhinologist. Mr. Wray treated

his cases in the following way. He injected cocaine by Mellen's method, and instilled a drop into the conjunctival sac. A Bowman's probe was then passed into the sac and the point pushed forward under the palpebral ligament. He then cut down on the guide, taking care to note the click of the knife on the probe. So far the procedure was quite painless. He then placed crystals of novocaine in the sac and had recourse to probing. At times, if the stricture was impermeable he forced a passage through the posterior wall of the duct. A piece of strapping was then placed just below the sac, so that the style did not press on the skin. A special style—gold-plated, and obtainable from Courlander, of Croydon—was then passed, and the latter was so constructed that when a piece of strapping was placed on its arms it could not move. Whilst it was *in situ* argyrol 5 per cent. was used three times a day, or such other application as might be desirable. Later, when a firm-edged fistula had formed, the patient was instructed to irrigate the sac three times a day, passing the style at night, and taking it out in the morning. To cure the fistula it could be dilated, and whilst stretched all the cicatricial tissue cut away, after which the edges of the wound were brought together and covered with collodion. He proceeded to criticise the operations of Toti, Eichen, and West. The first of these consisted in making a large open window between the sac and the nose, and as the nose in cases of lacrymal obstruction was so very often diseased the operation, in his judgment, could scarcely receive the approval of ophthalmic surgeons. And the patient experienced considerable annoyance on blowing his nose, and the operation provided no vertical tube like the duct to carry a flow of tears opposed to the entry of organisms to the sac. Eichen side-tracked the tears to the antrum —i.e., converted this cavity into a pool of stagnant tears. It also had the same objections as those urged against Toti's operation. West's operation was for obstruction low down in the duct, and consisted in removing its nasal wall. It was better than the two foregoing operations, as some of the duct was left, but it had the serious objection that autolavage and autoprobing were impossible. The aim of the operation was to make a permanent fistula in the middle meatus, but the task of making one in erectile or semi-erectile tissue in a canal the size of a crow-quill was almost impossible; but in the event of the duct being kept open by constant probing *vid* the nose, or canaliculus, the erectile tissue would be so damaged that a fibroid stricture would be bound to follow. Mr. Wray said that his object was not so much to attract attention to his own operation as to obtain a formal expression of opinion as to the value of the newer operations of Toti, West, and Eichen.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Vital Principles of Foodstuffs.—Paratyphoid Fever.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 7th, Dr. T. WARDROP GRIFFITH, the President, presiding.

Dr. J. GORDON SHARP read a short paper on the Vital Principles of Foodstuffs, with special reference to their employment in treatment. He said that he thought there might be something in Funk's statement that he had discovered a pyrimidine-like body which was related to thymine. This body was named "vitamine." Dr. Sharp believed in unboiled milk for children exclusively fed on that fluid, and he warned against the use of all dried milks, and, indeed, against all dried and tinned preparations. He also said it was necessary to guard against the use of foods which had been chilled or frozen for long periods. As remedies, he said, lecithins, glycerophosphates, and the nucleins were of little avail in the treatment of malnutrition, but he said that the crude foodstuffs, such as a mixture of eggs, fat, bone-marrow, and malt extract, did good. He had also great faith in cod-liver oil, and used it in combination with egg (both yolks and whites), and found it useful in all kinds of wasting. Fats had an important action in preventing and curing scurvy, scurvy rickets, and marasmus.—The paper was discussed by Dr. T. CHURTON and Mr. F. H. MAYO.

Mr. A. E. LITTLE read notes on a case of Paratyphoid Fever. The patient, a man aged 38, had a rise of temperature every evening for about two weeks before it reached 104° F., when rose-coloured spots appeared. Widal test for typhoid was negative, but positive for paratyphoid. The case was notified as continued fever on account of the character of the temperature, which came down gradually for four weeks before reaching normal, when there was a relapse, with a rise of temperature for a few days. There were nausea and vomiting occasionally in the early stage of the illness; no diarrhœa; duration of rose-coloured spots was shorter than typhoid. The diagnosis of paratyphoid fever must be made by the agglutination reaction.

The PRESIDENT showed Drawings of the Heart from a case of Patent Ductus Arteriosus.

Mr. R. LAWFORD KNAGGS showed a case of Intractable Vesico-vaginal Fistula following Parturition, in which the left ureter was implanted into the rectum by a sacral operation and the right kidney subsequently removed four and a half years ago. The patient had remained well, but returned to hospital recently suffering from prolapse of the upper and anterior walls of the bladder through the vesico-vaginal opening.

Mr. J. A. COUPLAND showed a specimen of Tuberculous Stricture of the Ileo-cæcal Valve which had produced acute intestinal obstruction. The case was treated by excision of the cæcum, ascending colon, and a portion of the ileum, followed by an end-to-end anastomosis, with a satisfactory result.

Mr. COUPLAND also showed a specimen of a Cystic Appendix which had become adherent to the sigmoid flexure and had given rise to strangulation of a loop of small intestine.

Mr. J. F. DOBSON showed a case of Ankylosis of both Hip-joints in the Flexed Position, following acute suppurative arthritis. A subtrochanteric osteotomy was performed on the left side; on the right side arthroplasty was performed on the lines laid down by Dr. Murphy, with an extremely satisfactory result.

Mr. ALEX. D. SHARP showed a case of Pharyngeal Tuberculosis in a woman aged 34, confined chiefly to the right half the pharynx. There was no clinical evidence of pulmonary phthisis, and only during the last few weeks the upper boundary of the larynx had become involved. Agonising pain on swallowing was relieved by local application of pure lactic acid every third day.

Cases were also shown by Mr. H. COLLINSON, Dr. W. GOUGH, Dr. CHURTON, and Mr. G. CONSTABLE HAYES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Pathology and Treatment of Dropsy in Relation to Colloids.

A MEETING of this section was held on Oct. 31st, Dr. J. O'CARROLL, the President, being in the chair.

Dr. WALTER G. SMITH read a paper upon the Pathology and Treatment of Dropsy in Relation to Colloids, in which he developed some recent views upon the causation and pathology of œdema and dropsical effusions. The chief factors of œdema were these: 1. Vascular—i.e., blood-vessels and lymph-vessels. (*a*) Increased supply or inflow of transudate. (*b*) Obstructed or diminished outflow through (i.) lymphatics; and (ii.) veins and capillaries. 2. Osmotic pressure. 3. Physico-chemical alterations in the blood. 4. Alterations in cell nutrition: (*a*) Blood-vessels and lymph-vessels; (*b*) tissue cells; and (*c*) nervous influences. 5. Turgescence of cells. Special emphasis was laid upon the condition of watery turgescence of cells, and illustrative experiments were shown in favour of the hypothesis of Martin H. Fischer (Cincinnati) that even a very slight degree of, or increase in, acidity leads to turgor of cells. Renal and cardiac dropsy were respectively discussed, mainly from the colloid chemical point of view, and the bearings of this idea upon treatment were pointed out.

The PRESIDENT remarked that the paper was a most valuable one, and rare in the history of the Academy. Referring to the possibility of œdema occurring without any discoverable fault of the kidneys or heart, he directed attention to a form of acute moderate dropsy met with in alcoholic cases without any sign of renal difficulty when examined by ordinary methods. This condition was found to clear up rapidly after a few days' rest. The rarity of œdema in cases of mitral stenosis, and its frequent occurrence in connexion with mitral regurgitation, was a matter of interest. With regard to the evil effect of saline purgatives in Bright's disease, it struck him that possibly it might be that the normal tendency of the kidney to get dropsical itself may be increased by the absorption of the common salt—sulphate of magnesium—which was so often administered in cases of dropsy. He was also struck by the evil effect of normal saline injections in inflammatory conditions, especially in acute pneumonia.

Professor W. H. THOMPSON inquired if all œdema included in the definition meant accumulation of fluid in the tissue spaces. He pointed out that tissue fluid was different from the fluid present in the lymph channels. The inhibition idea was not, he thought, brought home so closely to the circumstances as one would like, and it must be admitted that there were other factors which were potent in causing œdema. Alteration in capillary pressure certainly produced no influence on increase of fluid in tissues, except in the case of the liver. He considered that alteration in the capillary pressure without alteration in the cell walls had no influence in the production of œdema.

Dr. A. R. PARSONS, Dr. W. M. CROFTON, and Dr. H. T. BEWLEY also spoke.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Nov. 7th, Dr. David Ross, the President, being in the chair.—Dr. W. Langdon Brown read a paper on Recent Work on Glycosuria. A case was shown to illustrate the recently described type of renal glycosuria which approached the conditions produced experimentally by phloridzin poisoning—i.e., an undue permeability of the kidney to sugar, while the blood contained less sugar than normal. Apart from the glycosuria the patient showed no symptoms whatever and was increasing in weight. The importance of the internal secretion of the pancreas in carbohydrate metabolism had recently been emphasised by the observation that in the depancreatised dog the heart lost its normal power of utilising sugar. The difficulty of associating the pancreas with the glycosuria in some cases was due to the fact that the pancreatic lesion might not be in an active stage at the time the glycosuria was noted, and examples were given of this. Again, the pancreatic defect might not be absolute, but merely relative, owing to overaction of some antagonistic ductless gland, such as the suprarenal, thyroid, or pituitary. Loewi's adrenalin eye test for pancreatic insufficiency was based on this antagonism, and might enable us to determine whether a given case of glycosuria was due to the pancreas. Organic disease of the suprarenals did not cause glycosuria because it was accompanied by a deficiency of adrenalin, but the use of adrenalin in asthma might produce glycosuria, and the suggestion was made that some cases of high blood pressure with glycosuria in later life might be due to overaction of the suprarenals. Overaction of the thyroid, as in Graves's disease, was frequently accompanied by glycosuria, or at any rate by lowered tolerance for sugar, and the medicinal administration of thyroid extract would not infrequently excite glycosuria. With overaction of the pituitary body such as occurs in the early stages of acromegaly glycosuria was often present, while in the later stages when the posterior lobe of the gland had been destroyed there was a raised tolerance for sugar. A case of arrested acromegaly was shown in support of this, a woman who could consume 256 grammes of dextrose at one time without excreting any. After experimental ablation of the gland subsequent removal of the pancreas would no longer excite glycosuria. Puncture of the fourth ventricle excited glycosuria through irritation of the suprarenal and pituitary body. The clinical equivalent of this was seen in the glycosuria of cerebral hæmorrhage, tumours of the brain, and concussion. In an unconscious person the discovery of glycosuria was no evidence of diabetic coma, unless there was diacetic acid present as well. The conception of glycosuria which held the field to-day was a loss of balance between the internal secretions. In treatment the aim was not simply to find a carbohydrate-free diet, for diabetics could often metabolise some form of carbohydrate, such as potatoes, oatmeal or lævulose, while meat proteins might excite glycosuria mainly by their stimulating effect upon metabolism. Cooked eggs and vegetable proteins did not have this effect. Wheat flour was not well borne, and the greatest difficulty was to find a satisfactory substitute for bread. Pure gluten bread was nearly always badly borne, and it was better to allow a small amount of some ordinary bread or of a gluten bread containing sufficient starch to be palatable. The citrates replace carbohydrates to some extent, as may alcohol, as whisky, 1 oz. per diem. To check the onset of acidosis alkalies should be given, but not of one metal alone, or those not given may be drained from the patient. A mixture of sodium bicarbonate, potassium citrate, calcium lactate, and magnesium carbonate was advised to be given, in

dose and frequency in proportion to the condition of the patient. When any increased restrictions of diet were imposed alkalies should be given to protect the patient. In impending coma the bowel should be washed out and 4 per cent. of sodium bicarbonate with 3 per cent. lævulose in a litre of water administered by drop enema.—A general discussion followed.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.—A meeting of this society was held on Oct. 29th, Dr. J. Walton Browne (Belfast) being in the chair.—Mr. C. A. Adair Dighton (Liverpool) read a paper on Some Interesting Cases Treated in a Provincial Clinic. The cases he reported were of cavernous sinus thrombosis, latent cerebellar abscess lighted up by the mastoid operation, osteochondroma of the auricle, labyrinthitis and meningitis following polyp extraction, and symptomless lateral sinus thrombosis.—The paper was discussed by Mr. Charles J. Heath, Dr. Walton Browne, Dr. F. Spicer, Dr. J. Coubro Potter, and Dr. J. Walker Wood.—A paper by Dr. H. D. McCulloch on the Therapeutics of Radio-active Agencies in Disease, with special reference to the Cure of Chronic Nerve Deafness and Deaf-Mutism, which had previously been circulated among the Fellows, was discussed. Dr. McCulloch affirmed priority in the discovery in 1908 of this method of otological treatment, and submitted reasons why the hitherto employed medicinal and mechanical means had failed to remove the underlying cause. He deprecated inflation of the tubes in chronic catarrhal states until resolution had been effected *in situ* by radio-active agencies judiciously employed. Incidentally, he drew attention to the important immunising effect in subacute infections, referring to his previous contributions on that subject and to the amount of corroborative evidence that had since accumulated abroad. He exhibited and described various minute apparatus in the application of radio-active agents, mentioned his gratifying experience in a typical case of Ménière's vertigo, and drew attention to the promise of success this method held out in preventing deaf-mutism, the notes of one case being given. The paper was concluded by a tabulated list of 64 cases of hopeless deafness treated by him in 1911.—Dr. Walton Browne drew attention to a case of oto-sclerosis, reported at the recent International Otological Congress, markedly benefited by radium. In this case the improvement had been maintained.—Mr. Heath congratulated Dr. McCulloch on his interesting and scientific paper.—Dr. Potter required further information as to the selective action of the rays.—Mr. Dighton discussed the paper entirely from the aural point of view, strongly objecting to the statement that this treatment promised success in the prevention of deaf-mutism, as this "was not only misleading, but on the fact of things impossible."—Mr. B. G. Pullin, Dr. Spicer, and Dr. Wood joined in the discussion, the last-named stating that he had seen four of Dr. McCulloch's cases and tested them before and after three months' treatment, and though the hearing had not much improved there was an improvement.—Dr. McCulloch replied.—Mr. Charles Heath gave a demonstration of the Usual Methods of Drainage of Suppurating Ears. He said that a persistent discharge from an ear is uniformly accompanied by disease in the mastoid antrum, no matter whether the discharge escapes through the tense or through Shrapnell's portion of the drumhead. He pointed out (and illustrated his statement by moist specimens, diagrams, and patients) that when discharge escapes through a perforation in Shrapnell's membrane the change of route is due to the fact that the channel leading down to the tympanum, inside the incus, is obstructed by swelling of the mucosa of the inner attic wall, and that if the parts outside the incus (including Prussac's space and Shrapnell's membrane) were not unduly weak and capable of being perforated by the pressure of the pus that complete obstruction and acute mastoiditis would result. He exhibited diagrams of swollen mucous membrane obstructing drainage through the Eustachian tube, the tympanum, the attic, and the aditus, and described the symptoms they each produced. Mr. Heath stated that he had treated a considerable number of cases with perforation in Shrapnell's membrane, and while upon the operating table they all proved to be cases of mastoid disease draining on the outer side of the incus instead of (as usual) inside it; pathologically they were, therefore, not cases of attic disease at all. He asserted that it is only when discharge from the antrum descends inside the incus that it is able to reach the tympanic cavity and escape thence in the usual way through a perforation in the membrana tensa. Mr. Heath referred the Fellows to his article in THE LANCET of April 27th, 1907, where he recorded other cases of this kind which were afterwards exhibited before the British Laryngological and Otological Society.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The autumn meeting of the Northern and Midland Division of this society was held by the courtesy and at the kind invitation of the visiting committee at the Borough Mental Hospital, Leicester, on Oct. 23rd. Dr. J. F. Dixon presided.—Dr. T. Arnold Johnston read a very interesting paper on the Position of Pathology in Mental Hospitals. He referred to the difference in psychological ideas to-day as compared with formerly. He dealt with the relation of the medical superintendent and the medical officers to laboratory and research work, and to the ordinary routine duties of an asylum. He considered that the "incubus of routine" stifled ambition, and thought the medical officer needed encouragement and training to obtain his help in laboratory work, and that the pathological department ought to cover both ordinary sick-room work as well as special mental hospital conditions. There was need of a system of educating and interesting the medical officer; of a series of centres for the higher technical forms of laboratory work; and of an interchange and collating of proved research facts and their application to treatment. Altogether the paper brought forward many interesting and important points.—Remarks followed by Dr. J. F. Dixon, Mr. H. J. Blakesley, Dr. B. Pierce, Dr. C. A. Bryan, and others.—In the absence of Dr. H. D. MacPhail his paper on Some Observations on the Cerebro-spinal Fluid was read by Dr. C. H. G. Lyall. He dealt with the results of an estimation of the amount of albumin in the fluid from a series of cases of various forms of mental disorder. He used 5·5 c.c. of the fluid diluted with an equal quantity of water, the fluid being obtained by lumbar puncture. The amount of albumin present was found to vary within wide limits, the lowest being 0·03 per cent. and the highest 0·3 per cent. General paralysis always showed an increase. He considered the test of value in all classes of mental diseases and had found that the greater the amount

present the more serious is the prognosis of the case.—The meeting terminated with hearty votes of thanks to Dr. MacPhail for his paper, to the visiting committee of the hospital, and to Dr. Dixon for their kindly welcome and hospitality.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 5th, Mr. R. G. Hogarth, the President, being in the chair. The subject of Mr. Hogarth's presidential address was Some Nottingham Doctors. One of the most famous of all Nottingham doctors was, he said, John Arden, who practised at Newark from 1349 to 1370, and eventually became the King's surgeon. He was renowned for his cure of fistula in ano. In the sixteenth century Dr. John Jones, of Aspley Hall, was one of the first to draw attention to the value of the baths at Buxton. Dr. Robert Thoroton and Dr. Charles Deering were more renowned as historians than as doctors. Nottingham boasted of another physician appointed to Royalty in Dr. Taylor, who was physician to George II. The foundation-stone of the General Hospital was laid by John Smelley in 1781, and the hospital was opened in 1782 with 44 beds. The address was illustrated by numerous anecdotes and prescriptions of various past doctors.

Reviews and Notices of Books.

A Manual of Surgical Treatment.

By Sir WATSON CHEYNE, Bart., C.B., D.Sc., LL.D., F.R.C.S. Eng., F.R.S., and F. F. BURGHARD, M.S. Lond., F.R.C.S. Eng. New edition, entirely revised, and largely rewritten with the assistance of T. P. LEGG, M.S. Lond., F.R.C.S Eng., and ARTHUR EDMUNDS, M.S. Lond., F.R.C.S. Eng. In five volumes. Vol. IV.: *The Treatment of the Surgical Affections of the Jaws, Tongue, and Alimentary Canal.* London, New York, Bombay, and Calcutta: Longmans, Green, and Co. 1913. Pp. 622. Price 21*s.* net.

THE fourth volume of this admirable work maintains the high character of the previous volumes; it has been thoroughly revised, so that it is representative of present-day practice. It contains an account of the surgery of the jaws and of the tongue, and also of the whole of the alimentary canal.

In the description of the treatment of any morbid condition the authors mention briefly the various methods which have been performed for its relief, but they describe fully only one or two of the methods—namely, those which they consider to be of real value, not hesitating to condemn methods of which they do not approve; and though exception might be taken here and there to the strictures which they pass on these latter procedures, on the whole the course adopted is wise, for it represents truly the advice they give as to treatment. Every surgeon will prefer that method of operation which he habitually practises, and he will obtain better results with it than with a method which he seldom employs, and so it will happen that he will consider his own method the better operation. For instance, in the account of the operation for piles the authors, while praising the operation of the clamp and cautery, speak slightingly of the method of ligature, but any surgeon who has much employed the ligature method knows that its results cannot be surpassed when the operation has been performed by one thoroughly conversant with it. We are not disputing the opinion of the authors that the clamp and cautery method is good, for it is an excellent one, and is especially associated with King's College Hospital, whence this work emanates; but we maintain that the ligature method is also capable of giving perfect results. This work, however, is intended to be the expression of the views of its authors, and those who follow the advice laid down in this book will not go wrong.

In the chapter dealing with inflammatory affections of the rectum we are told that stenosing proctitis is usually due to syphilis; this was at one time generally held, and many hold it still, but there is a good deal of evidence that many cases, probably the majority, are not syphilitic, and in most cases antisyphilitic treatment is absolutely useless. The description of enucleation of the tonsil represents it as a more serious operation than it is generally held to be at present, for many surgeons prefer it to tonsillotomy.

It is only here and there in this large volume that we may reasonably complain that the advice given is not sufficiently definite. For instance, in the account of the treatment of tonsillitis the reader is told, *inter alia*: "Some surgeons used to place great faith in the administration of tincture of aconite given in minim doses, repeated every hour for four or five doses until the pulse-rate approached the normal." But there is not a word of advice as to whether the reader should follow the practice of some old surgeons or not; the phrase, "used to place great faith," suggests that this method of treatment is not used now; if this is so, why is it mentioned at all? Shall the reader adopt this treatment or not? Surely it would be wiser either to say nothing about it or to advise its adoption.

The illustrations are numerous and good.

Diseases of the Liver, Gall-bladder, and Bile-ducts.

By HUMPHRY DAVY ROLLESTON, M.A., M.D. Cantab., F.R.C.P. Lond., Senior Physician to St. George's Hospital; Formerly Fellow of St. John's College, Cambridge. Second edition, illustrated. London: Macmillan and Co. Pp. 811. Price 25*s.* net.

ON its first appearance Dr. Rolleston's book at once established itself as an authoritative work of reference upon diseases of the liver, gall-bladder, and bile-ducts; indeed, it was generally recognised as the most important work upon these subjects in English. The second edition appears in slightly different form and it is issued by a different publisher. It has been revised and brought thoroughly up to date, so that it will worthily maintain the reputation achieved by its predecessor. Each morbid condition is described exhaustively, and special attention is devoted to pathological anatomy and histology, which are illustrated by clear and useful plates, drawings, and microphotographs. A special feature of the book is the clear and scientific manner in which Dr. Rolleston discusses the etiology and pathology of each condition, and where these matters are in dispute he always presents rival explanations or theories with admirable lucidity and gives his own conclusions or opinions critically and logically worked out. Authorities are plentifully quoted on almost every page and in each instance a full reference is given in a footnote. Statistics, either personal or collected from various sources, are frequently referred to, and in many instances brief records of illustrative cases printed in smaller type are given.

In a book of this size it is impossible to review

the individual subjects treated of adequately within the space available. We can only refer to some of the conditions described and discussed. Dr. Rolleston alludes to the conception of functional disease of the liver, and points out that while the symptoms formerly ascribed to functional inefficiency of the liver are now capable of explanation by other conditions, such as indigestion, constipation, or auto-intoxication, yet it is probable that this condition may be responsible for many symptoms in view of the complex and many-sided activities of the liver. At the same time, in the present state of our knowledge, its existence is difficult to establish. The condition described by Pick as pericarditic pseudo-cirrhosis of the liver is carefully discussed, and is regarded for all practical purposes as an extreme grade of chronic venous engorgement of the liver in cardiac patients with adherent pericardium.

The difficult subject of the various cirrhoses of the liver is dealt with in an admirable manner, and the account and classification of these conditions are the best with which we are acquainted. After a general discussion of the various classifications proposed, Dr. Rolleston adopts for clinical purposes a broad division into two types—viz., ordinary, or portal, cirrhosis, with a rare sub-variety, pigmentary cirrhosis, and biliary cirrhosis, which is subdivided into hypertrophic biliary cirrhosis and obstructive biliary cirrhosis. The descriptions and discussion of the cirrhoses extend to over 160 pages, and include full accounts of the symptoms, complications, and accidents incidental to these diseases. In connexion with portal cirrhosis it is, as the author remarks, somewhat surprising to find from statistics that hæmatemesis occurs less frequently than jaundice, and that it is recorded in only about one-fourth of all patients dying with a cirrhotic liver. In regard to hypertrophic biliary cirrhosis he gives in his adhesion to the French school, who regard this condition as different clinically and pathologically from portal cirrhosis. He points out that it is distinctly rare, and he believes that cases of ordinary cirrhosis with large livers but without persistent jaundice are frequently mistaken for it. The existence of an obstructive biliary jaundice is carefully discussed in the light of experimental and pathological observations, and the origin of the fibrosis is fully considered. It would appear that there is very little evidence that biliary obstruction *per se* causes cirrhosis. The description of primary malignant growths of the liver is interesting, and a useful classification is given. The condition to which the name of cancer with cirrhosis was formerly applied is critically discussed, and Dr. Rolleston accepts the view formulated by Turnbull and Worthington, that the cirrhosis is the primary change and that a compensatory hyperplasia of liver cells occurs which eventually becomes excessive and atypical and thus develops into carcinoma. He therefore suggests that it should be called primary carcinoma supervening in a cirrhotic liver or cirrhosis maligna or carcinomatosa. The varieties of jaundice and the relation of this symptom to the diseases with which it is associated are fully discussed, and all the newer work upon these questions is incorporated.

Diseases of the gall-bladder and bile ducts are dealt with in the same critical and exhaustive manner as the diseases of the liver itself. The concluding section of the book is devoted to the subject of cholelithiasis. The etiology of this condition is carefully considered, and the varieties of gall-stones, their mode of production, and the symptoms and complications are all fully dealt with.

Dr. Rolleston's book is an admirable work of reference in every sense. It presents all the information obtainable from a very wide experience and an encyclopædic acquaintance with the literature of the subject in a practical, interesting, and readily available manner. In every instance the question of treatment is set forth in full detail, and where alternative methods are available their relative advantages are indicated. We feel confident that it will long remain the standard work of reference upon the subjects of which it treats.

Gonorrhœa in Women.

By CHARLES C. NORRIS, M.D., Instructor in Gynæcology, University of Pennsylvania. With an Introduction by JOHN G. CLARK, M.D., Professor of Gynæcology, University of Pennsylvania. London: W. B. Saunders Co. 1913. Pp. 521. Price 25s. net.

THE important rôle which the gonococcus is thought by some gynæcologists to play in the production of pelvic disease in the female is shown by the appearance of this monograph of 521 pages. It is naturally an extremely difficult matter to determine the exact number of patients suffering from gonorrhœa, and especially is this the case with gonorrhœa in the female. The published statistics with regard to the frequency of the disease vary very widely, and in many instances no reliance can be placed upon them, because no bacteriological examination has been carried out. In a number of the cases, moreover, such an examination yields no useful information, as the organism is not found, and yet it may well have been the original cause of the disease.

In the year 1901 a Committee on the Prophylaxis of Venereal Disease in New York considered the matter, and estimated that at that time there were 200,000 venereal patients walking the streets of New York. In 36 dispensaries and charitable institutions 14,649 cases of gonorrhœa were treated during the year, but this does not include a number of cases of complications, such as cystitis, venereal warts, and ophthalmia. It has been stated that 80 per cent. of all men in large cities have had gonorrhœa one or more times, that 45 per cent. infect their wives, that 80 per cent. of all operations upon women for disease of the uterus and adnexa are caused by gonorrhœa, and that 20 per cent. of all cases of blindness result from the same cause. Of about 12,000,000 people insured in Germany some 750,000 are annually infected with venereal disease. The author quotes a table showing that the incidence of venereal disease in the different armies of the world varies from 15 per cent. in the Bavarian army to 196 per cent. in the United States army, and a similar table for the navies shows an incidence-rate varying from 66 per cent. in the German navy to 160 per cent. in the American. These figures, even if they cannot be accepted without cavil, show that gonorrhœa occurs with almost incredible frequency, and it must undoubtedly be the cause of an immense amount of suffering and disability in the female sex.

In the chapter on the bacteriology and pathogenesis of gonorrhœa the author describes the best

methods of cultivating and staining the organism and illustrates its effects upon the pelvic organs. In the chapter on sociology the relationship of the disease to sterility and abortion and the important part it plays in the production of blindness are clearly demonstrated. The most interesting chapters are those in which the various methods that from time to time have been adopted in different countries to limit and prevent the spread of venereal disease are described, and in considering prevention the author would require a certificate of health for the male before marriage.

A very important chapter is that in which are described the various means of determining with certainty the presence of the gonococcus and its absence in cases of supposed cure. The pathological changes in the various parts of the genital tract are given in very full detail, and a large amount of space is devoted to a consideration of treatment, conservative and medicinal, radical and operative. A chapter which will be read with much interest is that on diffuse gonorrhœal peritonitis, an infrequent condition. The very important subject of gonorrhœa in connexion with pregnancy is dealt with in a separate chapter, and the prevention of ophthalmia is fully discussed.

For a writer believing, as Dr. Norris does, that the gonococcus is so potent an agent for mischief in the female it is of course difficult to restrict what he has to say on this subject, but it is a pity that he has not been able to place his views within a somewhat smaller compass. A notable example of the diffuse character of the book is the chapter on the treatment of pelvic inflammatory disease, which forms a most complete account of this subject whatever cause it may be due to. Then, again, it is a little difficult to see what precise connexion there is between gonorrhœa and the rupture into the peritoneal cavity or the torsion of inflamed uterine adnexa. All this, however, adds to the completeness of the book, and the author is to be commended for his industry and more particularly for the very full and excellent bibliography he has furnished.

Anatomy, Descriptive and Applied.

By HENRY GRAY, F.R.S. Eighteenth edition. Edited by ROBERT HOWDEN, M.A., D.Sc. Durh., M.B., C.M. Edin., Professor of Anatomy in the University of Durham. *Notes on Applied Anatomy.* Revised by A. J. JEX-BLAKE, M.A., M.B., B.Ch. Oxon., F.R.C.P. Lond., Assistant Physician to St. George's Hospital; and W. FEDDE FEDDEN, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon and Lecturer on Surgical Anatomy, St. George's Hospital. With 1120 illustrations, of which 431 are coloured. London, New York, Bombay, and Calcutta: Longmans, Green, and Co. 1913. Pp. 1311. Price 32*s.* net.

THIS edition marks a considerable advance on former issues, and whilst retaining all the old and well-tested features of a book familiar to so many generations of medical students, it has been brought well up to date and considerably improved. A welcome new feature is the inclusion of illustrations depicting the relations of the epiphyseal lines to the capsules of joints; these have long been wanted. We rather question, however, if the condition shown in Fig. 356 is that normal for the upper end of the ulna. The greatest alteration in the book consists of gathering together the paragraphs on surface anatomy into a separate chapter, and the considerable, and advisable, curtailment of the separate chapter on histology. But the feature which strikes us most is the nomenclature, and we take it as a strong argument for the concerted action of English-speaking anatomists in drawing up an accepted terminology that the editor has attempted a system which is peculiar to this particular work. It is an index of the chaos into which we have lapsed that some text-books adopt the B.N.A. in its entirety, some retain the old terminology, and that this particular one has a system all its own.

It is even difficult to determine the principles upon which this terminology is based. In some cases old names are retained—e.g., axis and odontoid process. In some cases they are entirely thrown over and trapezium becomes "the greater multangular bone," which sounds more terrible than the Latin of the B.N.A. In some cases literal translation of B.N.A. terms is attempted, with the result that such euphonious names as "conchal crest" and "chiasmatic groove" are evolved. Again, "carotid skein" and "coccygeal skein" strike us as failures in the attempt at direct translation. Uniformity is lost in some cases in translation—e.g., the B.N.A. "sulcus sagittalis" becomes "sagittal sulcus," whereas "sulcus transversus" becomes "groove for transverse sinus." Instances could be multiplied almost without end, but the multiplication would be a barren task, and it is enough to say that the terminology appears to us to be defective. This is not the fault of the editor, or of his assistants, but of the times.

Gray's "Anatomy" is a fine old work, and probably the best student's manual that we have at the present day; but the jangled condition of modern nomenclature has rendered an otherwise most excellent eighteenth edition a chaotic scheme of names. In a few years perhaps we shall regard this work as a brave pioneer effort which should have been attempted not by any individual, but by the English-speaking anatomical world.

A Monograph on Albinism in Man.

By KARL PEARSON, F.R.S., E. NETTLESHIP, F.R.C.S. Eng., F.R.S., and C. H. USHER, M.B., B.C. Cantab. Part IV.[1] Text, pp. 136 + xxii. Atlas, plates LIX. London: Dulau and Co. 1913. Price 21*s.* net.

THE fourth part of this monograph contains the magnificent collection of pedigrees of human albinos which has been formed and also one double plate of albino Pekinese spaniels. All the pedigrees are fully explained in the text, which gives also the name of the persons responsible for them. 654 pedigrees of human albinism appear on the plates, and in some of these hundreds of individuals find places. The Chassot-Ray families, which are shown in Fig. 640, Plate LIV., are recorded for eight generations. They were investigated by Cernaz in 1849 and 1850, and have been brought up to date by Dr. Usher, who made a special journey to Switzerland in September, 1909, for the purpose. The journey was, however, something of a disappointment, as albinism appears to have vanished entirely from the last three generations of these families owing partly to the fact that none of the albinos in the fourth and fifth generations left issue. The pedigrees are all neatly drawn, and not reduced so much as to make them difficult to interpret; but we question whether the system of drafting adopted is capable of showing the facts in the clearest method desirable. The symbols representing the individuals in each generation, sometimes 100 or more, are arranged equidistantly in long horizontal rows, the husbands

[1] The review of Part I. was published in THE LANCET of April 8th, 1911, that of Part II. on Oct. 18th, 1913. Part III. has not yet been issued.

and wives being included in the row. It is thus far from easy to tell at a glance which particular group of individuals belongs to each particular sibship. This is perhaps rather a trifling objection, as there is no real ambiguity. There are a few slight errors in the plates; of these some, but not all, are referred to in the list of corrigenda at the beginning of the volume. The absence of the reference number of one diagram on Plate LIV. appears to have escaped the attention of the authors. We draw attention to this because the pedigree is of rather special interest, as it shows a family in which albinism appears to have been latent for eight generations and then to have appeared in three individuals of one sibship. Besides the descriptions of the plates the text contains the bibliography of the monograph with its 700 entries. To some of these a brief note has been appended describing the relevant contents of the work referred to. We understand that the material collected in Part II. is to be statistically reduced and analysed in Part III.

It is a sad reflection that one of the authors, the late Mr. Edward Nettleship, should have died before the issue of the complete work. His great attainments and industry are a distinct loss to scientific work in elucidation of the problems of heredity.

Clinical Laboratory Methods: A Manual of Technique and Morphology designed for the Use of Students and Practitioners of Medicine.

By ROGER SYLVESTER MORRIS, A.B., M.D., Associate Professor of Medicine in Washington University, St. Louis. London and New York: D. Appleton and Co. 1913. Pp. 343. Price 12*s.* 6*d.* net.

THE number of problems on which the clinical laboratory is called upon to aid the physician or surgeon becomes greater every year, and as no one can carry all the details of the necessary procedures in his head continual reference is needed to a library of books dealing with chemistry, histology, and biology.

In the volume before us Dr. Morris has collected together the methods of examination most often called for, and has thus performed a most useful service to all clinical pathologists and to the students of medicine who work in their laboratories. The book deals first with the examination of the urine, setting forth the methods of identifying and measuring the various substances which may be contained in it—salt, albuminoids, pigments, ferments, and parasites—as well as describing the method of estimating the functional condition of the kidneys by the phthalein test. The gastric juice is next dealt with, the various test-meals being described, as also the procedures needed for investigating the stomach-contents when withdrawn; and the examination of the fæces is similarly set forth. Methods are here included for making permanent preparations of the intestinal worms. Chapter IV. deals with the sputum and Chapter V. with the blood, the concluding section being devoted to puncture fluids, including the cerebro-spinal fluid, in connexion with which the Wassermann test is described. Practical directions are given throughout for the performance of the different methods, the author's own knowledge of the matters with which he deals being evident, and references being frequently given to original articles in which the different methods were first described. There are a certain number of illustrations, chiefly of rarer objects such as animal parasites, but also of apparatus: they might perhaps have been more numerous with advantage.

We warmly recommend the book to those for whom it is intended.

Le Problème Physiologique du Sommeil.

Par HENRI PIÉRON, Directeur du Laboratoire de Psychologie Physiologique de la Sorbonne. Paris: Masson and Co. 1913. Pp. 520. Price 10 francs.

THE physiological problem of sleep is a subject on which countless minds have worked, not always with conspicuous discrimination or success, ever since man turned his attention inwards on the problems of his own organism. Physiologists and psychologists alike have propounded hypothesis on hypothesis, till probably more have been forgotten than are remembered; but we do not think that the difficulties in the way of its solution have been more clearly grasped, or an attempt towards that solution more lucidly expressed or more carefully worked out, than in the present memoir, which represents the researches of some 12 years.

The author remarks that it would be impossible now to propound a theory of sleep for which priority would not be claimed, even by "une voix d'outre-tombe," but he asserts with equal confidence that the facts on which such hypotheses should be based are conspicuous by their poverty. He has therefore devoted many years of experimental work to a determination of the actual factors involved in the oncoming of normal sleep, work based on a study both of human sleep and of the sleep of animals. The psychological aspect is left on one side, and attention is concentrated on the physiological phenomena, respiratory, circulatory, and sensori-motor, accompanying sleep. Valuable analogies are drawn from the pathological conditions of narcolepsy, lethargy, and somnolence, and from coma and comatose states. The hibernation of animals is also fully discussed. An elaborate description is next furnished of the physiological and histological modifications produced in animals experimentally deprived of normal sleep, and it is shown that during the artificial prolongation of the waking life a "hypnotoxin" develops in the serum and cerebro-spinal fluid of the animal experimented on. It is further shown that this toxin is not the banal toxin of fatigue; its injection into normal animals (into the fourth ventricle) is followed after some 30 or 40 minutes by an overwhelming and irresistible desire to sleep. The author shows commendable caution, however, in discussing the mechanism of this hypnotoxic effect. His view, briefly expressed, is that this hypnotoxin acts by setting free an inhibitory mechanism in cases where sleep is sudden and profound, while in cases of somnolence there is a direct intoxication of cellular elements, their functional activity being paralysed by a mechanism which is not nervous, but chemical.

The historical chapters on the theories of sleep are very interesting and instructive, nor are they without humour. There is no index of subjects, only one of authors' names; but there is a valuable bibliography of some 61 pages, containing, we calculate, some 2000 references.

The work is one of notable erudition, and it is at the same time lucid and readable. The author does not claim finality for his theory; indeed, he goes so far as to say that a toxic theory is not likely to be of universal applicability. Nevertheless, the experimental basis of his theory is highly elaborated, and the results are very suggestive.

Whatever may be the outcome of subsequent investigation, Dr. Piéron's book will take its place as one of the most scientific contributions to the study of the problem of sleep that have appeared in any language.

Der Blutdruck des Menschen: Ergebnisse der Tonometrie.

Von Dr. ARTHUR HORNER, Assistent der I. Medizin. Abtheilung des K.K. Allgem. Krankenhauses in Wien. Mit einem Vorwort von Professor Dr. J. PAL. 7 Abbildungen in Text. Wien und Leipzig: Moritz Perles. 1913. Pp. 198. Price 6 kronen.

Professor Pal explains that the author in his monograph has incorporated not only his own observations, but he had the use of the rich supply of material collected by Professor Pal himself during many years. After a short physiological introduction the author in the first or general part describes the "indirect" methods of estimating the blood pressure for clinical purposes, and in the second or special part he considers fully the variations of the blood pressures in a whole series of affections, such as infective diseases, diseases of the blood, circulation, abdominal viscera, in gynæcological and allied cases, nervous and surgical diseases, and many others. The illustrations leave something to be desired, both in execution and in number. The literature alone occupies 24 pages. The monograph is a most useful compendium as well as a storehouse of new observations on the blood pressure in man.

General Paresis.

By Professor EMIL KRAEPELIN, of Munich. Authorised English translation by J. W. MOORE, M.D. New York: Journal of Nervous and Mental Disease Publishing Company. 1913. Pp. 200. Price $3 00.

THE present volume consists of the chapter on general paralysis from Professor Kraepelin's "Textbook of Psychiatry" rendered into English. For this purpose it has been subdivided into seven chapters on the general symptomatology, clinical forms, post-mortem findings, etiology, nature of the disease, diagnosis, and treatment. It contains a full and readable account of the manifestations of the affection, and constitutes one of the most complete descriptions of general paralysis that can be found in any language.

Professor Kraepelin considers that tabes and general paralysis must be regarded as quite distinct, although the arguments which he advances are not convincing. There is no reference to the occurrence of the spirochæta in the cerebral tissues of general paralysis; it might have been inserted in a footnote by the translator, but possibly there was no opportunity for doing this. But all recent advances from the serological and other standpoints are fully dealt with. The translation is on the whole well done.

A Treatise on Materia Medica and Therapeutics, including Pharmacy, Dispensing, Pharmacology, and Administration of Drugs.

By RAKHALDAS GHOSH, L.M.S., Calcutta University, Lecturer on Materia Medica, Calcutta Medical School. Edited by D. H. DEARE, Lieutenant-Colonel, I.M.S., Professor of Materia Medica and Therapeutics, Medical College of Bengal. Fifth edition. Calcutta: Hilton and Co. 1913. Pp. 742. Price Rs. 5, or 7*s.* 6*d.*

IN our review of the fourth edition of this work (THE LANCET, March 18th, 1911, p. 745) we fully explained its nature and scope, and expressed the favourable opinion we had formed of it. The present issue has been ably edited by Lieutenant-Colonel Deare, I.M.S., and in the preface he acknowledges the valuable assistance he has had from Dr. B. N. Ghosh, the son of the author.

This edition has been brought up to date, and special interest attaches to the last two sections of the book dealing respectively with serum therapeutics and with organotherapy. Shiga's antidysenteric serum is discussed. Shiga claimed that by its use he had reduced the mortality from bacillary dysentery in Japan from 35 per cent. to 9 per cent., but in this work it is said that the experience of other observers does not support this statement. An adverse opinion is also given of the value of Yersin's antiplague serum.

The book is very conveniently arranged, especially for reference, and we believe that it will be found useful not only by Indian students and practitioners, but also by Colonial practitioners.

LIBRARY TABLE.

Le Radium: Son Emploi dans le Traitement du Cancer, des Angiomes, Chéloïdes, Tuberculoses Locales, et d'autres Affections. Par LOUIS WICKHAM et PAUL DEGRAIS. Paris: J. B. Baillière et Fils. 1913. Pp. 96. Price 1.50 francs.—*Radium as Employed in the Treatment of Cancer, Angiomata, Keloids, Local Tuberculoses, and other Affections.* By LOUIS WICKHAM and PAUL DEGRAIS. Translated by A. and A. G. BATEMAN, M.B., C.M. Aberd. London: Adlard and Son. Pp. 111. Price 2*s.* 6*d.* net.—The general idea of this small volume can best be described by quoting from the introduction: "What exactly is radium? Which are the diseases in which radium therapy can be useful? To what extent is radium useful in the treatment of cancer? These are the questions which are often asked at the present time, and which we propose to answer by the physical and medical facts within our experience. This work will be limited to a short exposition of the clinical properties of radium, and to a rapid survey of the researches and therapeutic results to which we have specially directed our greatest efforts." It will be seen that the book is not intended for those who specialise in radium, but rather for those who wish for an answer to the questions stated above. Consequently methods and technicalities are omitted; the physical aspect of the subject is stated briefly, but at sufficient length, and the main part of the book is devoted to an account of the diseases—notably cancer—in which the authors have had some success with radium treatment. Many very interesting cases are recorded, and a large proportion of these are illustrated, showing the condition both before and after radium treatment. Considering the great interest in radium at the present time, this book should meet with approval from a large number of the medical profession and not a few of the public. With regard to the English edition, we congratulate the translators on the pleasing way in which they have performed their task.

First Principles of Hygiene. By W. D. STURROCK, D.M. Oxon. Oxford: Clarendon Press. 1913. Pp. 256. Price 2*s.* 6*d.*—In this small volume Dr. Sturrock has presented very clearly a great deal of useful information on matters of personal, public, and domestic hygiene, subjects which he has throughout the book treated as far as possible as questions of applied physiology, and has incorporated with

elementary accounts of the bodily functions which may be affected by the hygienic measures discussed. The result is a very readable book which should be useful particularly to nurses, school teachers, social workers, and others who wish to obtain a working acquaintance with the principal doctrines and practices of sanitary science at the present day, and the reasons for their adoption. The facts and theories of hygiene which Dr. Sturrock gives are well and accurately presented. We may, however, take exception to his statement that in milk the fat should in any case come to 2·5 per cent. by weight. The official standard of fat below which adulteration is to be presumed in the absence of evidence to the contrary is 3 per cent., and this is usually regarded as a distinctly low limit. As in nearly all other works on hygiene, the author cannot refrain from describing and illustrating the D-trap, a contrivance which the most experienced sanitary inspector rarely sees outside a museum.

The Ophthalmic Year Book. Vol. IX. Containing a Digest of the Literature of Ophthalmology for the Years 1911 and 1912. Edited by EDWARD JACKSON, M.D., Professor of Ophthalmology in the University of Colorado. Illustrated. Denver: Herrick Book and Stationery Company. 1913. Pp. 518.—The Ophthalmic Year Book for 1911 and 1912 is well up to the standard we have been led to expect. The enormous labour involved in such productions is usually but scantily acknowledged by the support afforded to them, but the gratitude of those who find reason to use them is perhaps some reward. We notice that this publication depends upon the assistance of the Knapp Testimonial Fund of the American Medical Association. This is not as it should be, and we hope that better support will be accorded in the future. The Ophthalmic Year Book has only one serious rival—viz., Nagel's Jahresbericht für Augenheilkunde. We cannot say that it reaches the high standard attained by the German work, but the latter has two great drawbacks: its utility is limited to those who read German, and its publication is usually delayed till about two years after the date of the literature reviewed. On the other hand, English, and especially American, ophthalmic literature receives in the work under review a fuller measure of consideration, so that we have here a valuable link with our confrères across the Atlantic.

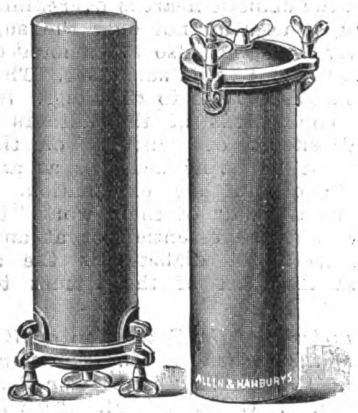
Handbook of Information regarding the Routine Procedure of the Division of Communicable Diseases, 1913. By J. S. BILLINGS, Jr., M.D., Chief of Division, Department of Health, City of New York. Published by the Department of Health, City of New York. Pp. 200.—This little work, besides fulfilling its aim of giving information to the medical profession of the City of New York and other parties concerned in the routine of matters relating to communicable diseases, will be of interest to students of comparative sanitation. Besides local information and ordinary routine administration in cases of communicable diseases as affecting the medical profession, institutions, hotel keepers, house owners, and the public generally, it deals in detail with tuberculosis, typhoid, cerebro-spinal meningitis, acute poliomyelitis, malarial fever, puerperal septicæmia, erysipelas, pneumonia, diphtheria, venereal diseases, glanders, and so forth. The technique of the various tests used is described. The sections on typhoid fever and venereal diseases are new. The method of through and through binding with metallic wire impairs the convenience of the book, as it requires a forcible effort with both hands to keep it open.

La Transplantation Restauratrice du Péroné après les Résections des Os Longs du Membre Supérieur pour Ostéo-sarcomes. Par le Dr. HENRY FAY, de la Faculté de Médecine de Paris; Interne de l'Hôpital Saint Joseph de Paris. Paris: A. Maloine. 1912. Pp. 140.—This pamphlet is decidedly above the average inaugural thesis, indeed it is a real addition to surgical literature. The tendency at the present time is entirely to excise a portion of a bone for sarcoma rather than to amputate; but the limb from which a large portion of a bone has been taken is rendered almost useless unless the damaged bone can be replaced. The fibula seems to offer itself for this purpose, as it may be removed from its natural site without any impairment of function, at least in adults. This treatise deals with the application of portions of the fibula to replace parts of the humerus which have been removed on account of the presence of malignant growths. Ten cases are recorded in which this operation has been performed, and a number of skiagrams taken after the operation show the good results obtained.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLVII., Nos. 1 and 2. Cambridge University Press. Pp. 1–148. Price 9*s.*—On the Production and Utilisation of Glycogen in Normal and Diabetic Animals, by E. W. H. Cruickshank. Minkowski in 1892 showed that after complete extirpation of the pancreas, in addition to glycosuria, there was a rapid disappearance of glycogen from the liver; even on the second day after the operation the liver was practically glycogen-free. The administration of glucose did not give rise to any accumulation of glycogen, while the administration of lævulose caused glycogen to appear in the liver. The author experimented on female dogs from 5 to 10 kgm. in weight. Depancreatisation was performed by Hédon's method. Details are given as to the method of estimating the glycogen in the liver and in the normal and diabetic heart. The author confirms Minkowski's observation as to the almost complete disappearance of glycogen from the liver, which becomes loaded with fat. The latter's results with lævulose feeding the author was unable to confirm. Normally the heart muscle contains about 0·5 per cent. of glycogen. Under conditions of increased activity the heart may use up its stored glycogen in a few hours. The diabetic heart contains considerably more glycogen than the normal heart. Activity of the heart evoked by adrenalin rapidly uses up the glycogen. After death, if the normal or diabetic heart be kept warm, glycogen rapidly disappears, due to a glycogenolytic ferment.—The Changes in the Reaction of Growing Organisms to Narcotics, by H. M. Vernon. The author describes the effects of a large number of narcotics—e.g., eight of the monohydric alcohols—esters and ketones. Great changes in the reaction of growing organisms to these and other narcotics were observed, which he suggests were probably for the most part dependent on changes in the composition of the cell lipoids.—The Volume of the "Dead Space" in Breathing, by A. Krogh and J. Lindhard. The authors criticise

the results of Douglas and Haldane, who from their experiments concluded that the "dead space" may be increased during muscular work to several times the resting volume. The Danish authors find, however, that the effective dead space in breathing is not appreciably altered during heavy muscular work and that the direct method of determining the composition of the alveolar air from samples taken at the end of inspiration and expiration becomes untrustworthy during muscular work.—The Nature of Thrombin and Antithrombin, by B. J. Collinwood and M. T. MacMahon. The authors used solutions of thrombin obtained by digesting well-washed sheep's fibrin for 24 to 48 hours in 5 per cent. NaCl. This thrombin is destroyed by heat (50—60° C.), acid, alkali, and liquor pancreaticus. Antithrombin, which is present in serum, was used. It is destroyed by heat (60—65° C.), acid, and will only act in an alkaline medium; neutralisation does not destroy it, but only inhibits its activity. The authors suggest that thrombin is a protein, and antithrombin a proteolytic ferment; while fibrin is a combination of thrombin and fibrinogen.—The Ileocæcal Sphincter, by Arthur F. Hertz. No mixing takes place under normal conditions between the contents of the small and the large intestines, so that fæcal matter that has once reached the cæcum can never return into the ileum. The sphincter prevents the contents of the ileum passing too rapidly into the cæcum. The author gives an account of some recent observations made with Alan Newton by means of bismuth and X rays.—The Normal Movements of the Colon in Man, by Arthur F. Hertz and Alan Newton. The authors record a series of interesting observations under X rays of six normal individuals whilst they were eating an ordinary dinner between five and seven hours after a bismuth or barium breakfast. On two occasions they observed a large movement of the colon.—The Action of Ions and Lipoids upon the Heart of the Frog, by A. J. Clark. This is a highly technical paper, of interest more especially to pharmacologists. The special apparatus for perfusing and recording the movements of the heart are described. The paper is divided into four parts, of which the first deals with action of kations by altering the ionic content of Ringer's fluid. The authors use the term hypodynamic state to indicate that state of the heart where the frequency remains nearly unaltered but the force of contraction and the rate of conduction are both decreased. The second part deals with the action of anions on the hypodynamic heart; the third with lipoid substances on the same condition of the heart. The fourth part is occupied with a discussion as to the mode of action of the substances that revive the hypodynamic frog's heart. The summary of results extend to nearly two pages.—W. B. Hardy contributes a short note on Differences in Electrical Potential within the Living Cell.—The Regulation of Respiration and Circulation during the Initial Stages of Muscular Work, by A. Krogh and J. Lindhard, so far as these refer to changes in ventilation, blood flow, pulse-rate, respiratory exchange, and alveolar CO_2 tension. Evidence is brought forward to show that the rise of ventilation, like the increase in heart-rate, is produced not reflexly but by irradiation of impulses from the motor cortex. As to ventilation, these impulses act indirectly through the respiratory centre by suddenly increasing its excitability towards hydrogen ions.—The Carbohydrate Metabolism of the Isolated Heart-lung Preparation, by S. W. Patterson and E. H. Starling. The now well-known heart-lung preparation obtained from dogs rendered completely diabetic by removal of the pancreas 2–7 days beforehand was used. A series of experiments was also made on the consumption of sugar by the isolated lungs in normal and diabetic dogs, serum being perfused. The lungs—normal or diabetic—use up glucose to about 1·3 to 1·5 mgm. glucose per gramme of heart muscle per hour. The figures for the consumption of sugar in normal hearts are extremely variable. Both in the diabetic and the normal heart the authors by the method of comparative blood analysis were unable to arrive at any definite decision as to the consumption of sugar by the heart muscle. If, however, the diabetic heart is over-stimulated with adrenalin, it uses up not only the sugar in the circulatory blood, but also the amount of glycogen previously stored in its substance. The increased utilisation was not due to the lungs. Some of the previous conclusions of the authors as to the beneficial effects of pancreas on the diabetic heart "must be abandoned," or at any rate are susceptible of another explanation. They are inclined as a result of their work "to abandon the view that the essential, or at any rate the primary, factor in diabetes is the absence of power on the part of the tissues to consume sugar."



The Quarterly of the Federation of State Medical Boards of the United States. Edited by OTTO V. HUFFMAN. Federation Press, Easton, Pennsylvania. Vol. I. No. 1. October, 1913. Price 50 cents.—The first issue of this publication is naturally mainly of local interest, though a perusal of several of the articles shows not a little that is of interest to all who are especially concerned with the subject of medical education in general. Among these may be mentioned the articles on the Homœopath's View-point of Medical Education, by Dr. Royal J. Copeland; Rules and Regulations Governing Examinations, by Dr. John M. Baldy; Discipline of the Character in Medical Education, by the Hon. Justice Eugene A. Philbin; and Universal Reciprocity, by Dr. Beverley Robinson.

AMERICAN ASSOCIATION OF IMMUNOLOGISTS.—This society was organised on June 15th at Minneapolis, with 41 original members, all of whom have been pupils of Sir Almroth E. Wright, of London. The objects of the society are as follows. To unite the physicians of the United States and Canada who are engaged in the scientific study of immunology and bacterial therapy; to study the problems of immunology, and to promote by its concerted efforts scientific research in this department; and to spread a correct knowledge of vaccine therapy and immunology among general practitioners. The officers temporarily chosen are: Dr. Gerald B. Webb (Colorado Springs), president; Dr. George W. Ross (Toronto), vice-president); Dr. Willard J. Stone (Toledo), treasurer; and Dr. Martin J. Synnott (Montclair), secretary. A council of five members was also selected, whose duty it will be to manage the affairs of the society in the interim of the meetings. This council is made up as follows: Dr. A. Parker Hitchens (Glenolden), chairman; Dr. J. Robinson (Temple, Texas), Dr. Oscar Berghausen (Cincinnati), Dr. Campbell Laidlaw (Ottawa), and Dr. Henry L. Ulrich (Minneapolis). The first annual meeting of the society will be held on June 1st, 1914. This is Monday of the week of the annual session of the American Medical Association, and it will be held at the same place. The programme will be made up of original papers dealing with the different branches of vaccine therapy and immunology.

New Inventions.

A STERILISER-TANK FOR INSTRUMENTS.

I HAVE found the steriliser-tank shown in the illustration very useful when operating in private, as it obviates the trouble and delay which occur when it is necessary to get things ready in the patient's home. This steriliser-tank is a cylindrical vessel 11 in. high and 3½ in. inside diameter, fitted with a lid, which is clamped on by three thumbscrews fixed to lugs which are riveted to the cylinder, like the lid of a high-pressure steriliser. In the centre of the lid is a hole which is closed by a screwing plug. The tank is boiled over a Bunsen or Fletcher burner, the instruments placed inside, and the lid, *with the plug removed*,

clamped on. When sufficiently boiled a portion or all of the water is poured off, all that is necessary to do this being to stand the steriliser upside down over a basin; it will rest quite securely on the screws, which act as a stand. When empty, some lysol, spirit, or other solution can be poured through the hole in the lid, the plug screwed in, and the container placed in the bag with the instruments ready to be turned out at the time of the operation, sterilised in readiness for use. When properly screwed up the steriliser-tank is quite water-tight.

The apparatus, which has been made for me by Messrs. Allen and Hanburys, Limited, Wigmore-street, London, W., is of such a size that it will take any ordinary sized instruments required for almost any major operation.

Harley-street, W. THOS. NORTH, F.R.C.S.Irel.

A PORTABLE X RAY PLANT.

Mr. H. Vogelsberg, a practical electrician, writes as follows:—

"In conjunction with Dr. J. W. Hodgson, of Exmouth, I have designed a portable and self-contained X ray apparatus, the purpose of which is to enable a radiogram to be taken at a patient's residence, and thus save a large amount of unnecessary discomfort or suffering in conveying him to the nearest X ray plant. In time of war it could be used in the open field for examination and location of bullets in the wounded. The car on which the generating plant is erected is a 1906 15–19 h.p. four-cylinder Coventry Humber, the flywheel of which is very convenient for driving a dynamo, as it is situated directly under the forward part of the footboards. Three steel T girders are fixed under these boards from the main framework so as to take the weight of the dynamo. When the latter is placed on the car it is raised off a small truck on which it rests when not in use by means of a Weston hoist, and pulled along an overhead rail provided for the purpose in the motor-house until over the position which it has to occupy in the car, and lowered on to its bolts. These bolts can be removed when the car is not required for X ray work. After the car has been driven to the place where it is to be used, the belt is passed round the flywheel and the ends fastened together over the pulley. The dynamo is raised, and the belt made taut by turning round the hand-wheels provided for the purpose, a lock-nut keeping all tight. The dynamo is a continuous current machine, and was supplied by the Cavendish Electrical Company, London. It has an output of 75 volts 12 ampères at 1250 revolutions per minute. The pulley fitted to it is in ratio to the flywheel as one to two; but it would be an advantage to fit a larger pulley on the dynamo shaft, as a steadier speed could more easily be maintained with the engine running faster. The current on leaving the dynamo is carried to the switchboard and passes through the main switch, ampèremetre, and fuse, to the terminals of the switchboard. The mercury interrupter is of the ordinary jet pattern, working in a non-oxidising gas, the gas being carried in a bladder. This type of interrupter has undoubted advantages, but if absolute simplicity is aimed at, one working in oil would be perhaps preferable. The interrupter is worked by a small electric motor, the power for which is brought from the switchboard by means of a flexible wire. Both motor and interrupter are fastened down upon a shallow box which contains the condenser. The advantages of having the interrupter outside the patient's house are twofold: firstly, the elimination of noise; secondly, the man in charge of the motor and plant can look after it and see that it is working properly and well, thus leaving the medical man free. The conductor used for carrying the electricity from the generator to the house is a 7/21 twin cable, carried on a reel in a cable-box. A binding screw is fixed on each end of the real axis, and the inner end of the cable is permanently connected with these, so that only the necessary amount of wire need be unwound, the red end of the axis connected to the interrupter, and from that to the positive pole on the switchboard, and the black end direct to the negative pole. The framework of the couch is made of teak, as light as is possible to be consistent with strength, and can be raised or lowered at one end; the other end can be rested against and fastened by straps to the patient's bed, or can be rested on a trestle. A second switchboard is provided in the patient's room, and stands flat on the ground, a little to the right of the operator, who keeps his foot on a pedal switch. The pedal switch in normal position connects the resistance with the generator; when the pedal is depressed the primary of the coil is connected through the variable resistance. An incandescent pilot lamp gives warning when the current is flowing. The X ray bulb is fixed in a safety case, the inner portion of which is lined with lead oxide. Glass supports are fixed across the openings at each end of the box. An iris diaphragm is fitted over a circular opening on the top of the box, to allow adjustment during the use of the rays. The whole box stands on ball castors, so that it can be moved about under the couch into any position that may be required. The coil used is a Sanax 12 inch intensified coil, which works very well and is free from back currents. Although the apparatus described has not yet arrived at the state of perfection that one would quite wish for, there is reason to suppose that results as satisfactory can be obtained with it as with a fixed plant."

THE SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The annual general meeting of the Fellows and Members will take place at the College, Lincoln's Inn-fields, W.C., on Thursday, Nov. 20th, at 3 P.M. Mr. J. Brindley-James, president of the Society of Members, will move this resolution:—

That this twenty-ninth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College, which as now constituted only represents those Members who also hold the Fellowship; and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

Dr. A. S. Morton will move:—

That this meeting of Fellows and Members requests the Council to include in their next annual report a balance sheet showing fully and without reserve the assets and liabilities of the College on Midsummer Day, 1913.

A resolution calling for the immediate appointment of a special committee, composed equally of nominees of the Council of the College and of the Society of Members, has been sent in but ruled out of order. All communications should be made to Dr. Sidney C. Lawrence, honorary secretary, 22, Latymer-road, Lower Edmonton, N.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 15, 1913.

The Psychology of Railway Accidents.

IN the appalling series of railway disasters which have occurred within the last few weeks in this country and abroad, it is a very striking circumstance that in almost every instance the source of the accident has been traced to a failure in that human factor on which in the ultimate result the proper functioning of even the most ingenious mechanism must depend. These lamentable accidents have been so numerous, and the error or negligence of the driver or the signalman in each case has been so similar in character, that it is difficult to dismiss the suspicion that in this succession of catastrophes we have to deal with something more than a mere casual variation from the normal average of such events; and this suspicion will be strengthened when we take note of the many attendant circumstances which seem to indicate the operation of novel psychological influences, some of them of a more general character than can be explained by temporary conditions affecting a particular industry.

It would, of course, be absurd to found on even a larger number of such instances a general charge of inefficiency and recklessness; and a charge of this sort would be doubly unjust when, as in the present case, it would be urged against a body of public servants whose past record has been so admirable. But without making any such sweeping accusation, it is quite legitimate to inquire whether these instances of negligence may not be related to that ominous change in the mental outlook of the industrial classes of which there have been so many and such grave manifestations in the last few years. The suggestion might seem fanciful, were it not confirmed by the attitude in this connexion of those who claim, and apparently with authority, to speak for the mass of railway workers. The agitation for the release of the Aisgill driver, no less than the ferment excited by the arrest of the man responsible for the disaster to the Paris-Marseilles express, shows with painful clearness that in its latest phase the sense of corporate unity amongst railway servants has become associated with a lessened sense of responsibility towards the community at large. And the same spirit of cynical indifference to the common welfare, the same reckless pursuit of class interest is, of course, the very essence of the syndicalist movement, where the favourite weapon, the general strike, owes what efficacy it possesses to its power to inflict suffering on the public. But it is obvious that the mental attitude which accepts such methods, and which by their acceptance is strengthened and confirmed in its vicious direction, is fundamentally unhealthy and perverted, and by reason of its morbid character must react upon the whole disposition and activity of the individual who adopts it. The temper of syndicalism represents in the group something akin to the temper of paranoia in the insane personality; and just as the self-centred tendency of the persecutory lunatic warps his sense of proportion, makes him too keenly sensitive of his own rights and callous as to the rights of others and the duties which he owes to others, so does the collective paranoia of syndicalism lead to a similar loss of moral balance in the attitude of the given industrial group towards the community of which it should form a part. And this collective spirit naturally influences for evil the individuals who constitute that group; it fosters a state of emotional irritability, of impulsiveness, which is unfavourable to clearness of judgment and accuracy of perception, and which, therefore, might well contribute to such errors and omissions as those responsible for the recent epidemic of disaster. We are bringing no charge of recklessness, and certainly no charge of malice, against particular persons; but we suggest that the conditions of railway travel to-day require most careful attention, and the attention should not be focussed upon the details of this or that catastrophe.

It may not, then, be too fantastic a speculation to connect these sinister occurrences with the spirit of unrest which has pervaded the industrial world of late; and the mere possibility of such an influence should at all events serve as a warning against an attitude of passive acquiescence in the conditions which have brought that spirit into being. These wider aspects of the industrial problem lie outside the scope of this article, nor do they perhaps admit of being so fitly considered from the special point of view which is here adopted. But it may not be out of place to say that in dealing with them we should act on the principle which is the ideal of medical practice, the principle that treatment should be directed to causes rather than to symptoms. If industrial discontent and unrest are contributory causes of inefficiency and recklessness in individual workers, these causes are in their turn the effects of other causes, and it is to the removal of these deeper sources of evil that the efforts of social reform should be directed. And in this task a due consideration of the psychological factors of the problem will be an aid of no small value. Lying beneath most of the varied manifestations of disorder and eccentricity in modern life may be detected as a potent influence the difficulty of nervous adaptation to a too rapidly changing environment. Even the firmest believer in the essential capacity of the race would hardly maintain that human intelligence has progressed in a degree at all commensurate with the development and multiplication of the numerous instruments

devised and fashioned by those gifted and subtle intellects, whose discoveries have revolutionised science since the middle of the last century. It is to the new environment of ideas and sensations created by these discoveries, and by their practical applications, that we have to adapt ourselves to-day; and the process, alike for society and for the individual, must at best be slow and arduous, and will inevitably be attended with such occasional failures as find expression in the spread of social and industrial unrest, with an accompanying growth of neuroses.

Insured Persons and Herbalists at Worcester.

WE called attention last week to a decision of the Insurance Committee of the county borough of Worcester which by the vote of a majority, led by the chairman of the committee, decided to allow certain persons desirous of making their own arrangements for medical treatment under the National Insurance Act to do so with a herbalist. We may say at once that we regard the decision as a wrong one, not meaning merely that it is foolish and prejudicial to the insured persons for whose benefit the Act was passed, and for whom it is to provide "against loss of health and for the prevention and cure of sickness," but wrong in law according to every reasonable interpretation of the Act and the regulations made under it. The regulation under which the Worcester Insurance Committee came to the decision referred to orders that:[1] "The committee may allow insured persons resident in the county, whether individually or collectively, in lieu of receiving medical benefit under the regulations made by the committee, to make their own arrangements for receiving treatment (including medicines and appliances);" and the next regulation stipulates that where the committee shall be "of opinion upon such evidence as they think sufficient that the arrangements made by any person who has been required or allowed to make his own arrangements under this regulation are satisfactory—that is to say, such as to secure treatment (including medicines and appliances) not inferior in nature, quality, or extent to that provided under the arrangements made by the committee, and to comply in other respects with any conditions which by reason of any scheme for the distribution of Parliamentary grant must be complied with in the case of treatment provided otherwise, there shall be made towards the cost of that treatment such contribution calculated and paid in such manner as hereinafter in these regulations provided." If the Worcester Insurance Committee is right in considering that the above regulations allow it to spend the funds entrusted to it in paying herbalists or any other unqualified persons who pretend to treat the sick, we say without hesitation that it has discovered a way by which to stultify and reduce to ineffectiveness in particular instances a statute passed "to provide for insurance against loss of health and for the prevention and cure of sickness." We say in particular instances because we are satisfied that the good sense of the community will not allow it to entrust itself as a whole to quacks, Christian Scientists, faith-healers, and bone-setters; but at the same time we believe that one of the general objects for which the Act was passed was to protect or divert, both generally and in particular instances, members of the working classes from the dangers of recourse to unqualified advisers in matters concerning their health.

It may be pointed out that anyone, insured or not, may be treated by whomever he pleases, or by no one. But this is a question of treatment at the expense of the Insurance funds, and if these funds are to be distributed to persons for the express object of their being used to remunerate unqualified persons, there is no reason why druggists should not also be included among those with whom the insured may make their own arrangements. We do not mean to suggest that the registered pharmacists, who are doing such good work under the Act, not always upon highly remunerative terms, would wish to compete with herbalists for patients, but we suggest that they would be as well or better qualified to supply their patients with effective treatment. The matter, however, must depend not upon what the medical profession or the Worcester Insurance Committee or the framers of the Insurance Acts may consider right in principle, but upon what the Acts and the regulations made under it may provide. Obscure reference was made in the recent discussion at Worcester to utterances of a Cabinet Minister in the House of Commons and to dicta of the Insurance Commissioners; these clearly will not affect the question. The regulations from which we have quoted the material words do not say that persons are to be allowed to make their own arrangements for "treatment by duly qualified medical practitioners," or the matter would be beyond argument; they use the term "treatment" without qualification except by the parenthesis ("including medicine and appliances"). Reference to the definitions contained in the regulations from which we have quoted shows that treatment means "medical attendance and treatment of insured persons." Here again there is no direct reference to a "registered" or "duly qualified medical practitioner," but the latter description of those who are to be placed on the panel occurs in the opening words of Section 15 of the Act of 1911. And nowhere, we say with confidence, in the Acts of 1911 and 1913, or in the regulations either of the Insurance Commissioners or of the Board of Trade, is there the smallest reference, or hint or suggestion of a reference, to any kind of treatment being supplied under the Act, or at the expense of the

[1] National Health Insurance (Administration of Medical Benefit) Regulations, 1912, made under Section 15, Subsection 3, of the National Insurance Act, 1911, which also see.

funds provided by it, otherwise than at the hands of those for the testing of whose qualifications and for whose registration the State has provided.

In this connexion Subsection 4 of Section 15 of the Act is particularly to the point, but we might quote almost any section or regulation referring to medical benefit to the same effect. We need hardly add that every medical certificate purporting to be given under the National Insurance Acts or under any other Acts of Parliament, whether relating to sickness, death, or any other matter, is valueless unless it is given by a registered medical practitioner, and that as a general rule employers, Friendly Societies, and others who require evidence of the sickness or death of individuals in matters not regulated by Acts of Parliament are equally strict in their demands, under the guidance of ordinary prudence and good sense. As to the precise manner in which the question should be raised we are diffident in expressing an opinion, as we do not find the Insurance Acts explicit in providing for the settlement by the Commissioners of disputes between the minority of an Insurance Committee and a majority upon a point of law, as to which the latter is alleged by the former to have taken a wrong view. The Commissioners are, however, certainly interested in the question, because under Section 54 of the Act of 1913 they have to pay out of the National Health Insurance Fund sums required to meet expenditure "properly" incurred by Insurance Committees, and we have little doubt that upon the audit of the Worcester Insurance Committee's accounts the matter could be raised, if not referred directly at the present stage to the Commissioners. There is also the possibility of an application to the courts to prevent the improper expenditure of money by the Committee being the proper course, but we imagine that this would not be necessary unless the Commissioners declined to intervene in an advisory capacity or otherwise. As a result we predict with some confidence that the majority of the Worcester Insurance Committee will find that treatment by a herbalist is not medical treatment within the meaning of the Insurance Acts, whatever may be their personal views as to its being not inferior in nature, quality, and extent to that provided by the medical profession.

Reversion to Type.

THE greater part of THE LANCET this week is printed in larger type than any issue of the journal has ever been, with the exception to be mentioned, the form now adopted being a practical response to representations which have reached us lately from many readers. The larger type now employed, and for the future to be employed, is almost precisely the type in point of size in which THE LANCET made its first appearance one Sunday morning in 1823, and constitutes a reversion as accurate as most of the examples of that phenomenon which from time to time are illustrated in biological articles. Why the Founder of THE LANCET published his first number on a Sunday morning we have not the least idea; but considering the haste in which all the proceedings in connexion with the original issue of THE LANCET were taken, the probability is that the date of appearance was an accident, and that the selection of the original type had no better reason. Only for one year was the paper printed in a type which is just fractionally larger than the one in which this article is printed, for in November, 1824, the type was introduced in which from that date until November, 1913, THE LANCET has made its appearance. During these 90 years the number of representations to us that the size of the type was inconvenient has been, on the whole, not at all large, if we may make this deduction from a personal experience of about a quarter of that period; but the significant fact is that such representations as have reached us have nearly all been made within the last decade, and have certainly increased in number quite recently. There is no doubt now in our minds that our public will find a larger type agreeable and convenient, and we make the change therefore with pleasure, accompanied with a hope that the next revolution in our printing arrangements will, in accordance with precedent, be delayed for another 90 years. For we like to think that such longevity is assured.

From one old member of our staff among those to whom our intentions were mentioned recently, we received a communication suggesting that we were supplying a great example of racial decadence, inasmuch as, if the demands for a larger type to which we were proposing to accede were well founded, it was obvious that the sight of the medical profession at the beginning of the twentieth century was not so good as it had been during a large proportion of the nineteenth century. But we think that this whimsical protest against what he of course called "change for the sake of change" misses the reasons which underlie the desire of our readers for a larger type. If we may draw general lessons in sociology from such a concrete example as the alteration in the printing of a professional newspaper, we would say that we have here one more proof of the great necessity of the times in which we live—namely, the necessity of "speeding up." We telegraph and telephone instead of writing letters; we use machine-driven vehicles on road or rail instead of trusting to our legs or to our horses; and these things not so much to save ourselves trouble as to give ourselves more time in which to take further trouble. We do not recognise any decadence in securing freedom from friction where it can be obtained, when the resulting smoothness is expressed in a larger output of work. THE LANCET in its present guise is easier to read than it has been for 90 years.

Annotations.

"Ne quid nimis."

MINOR EPIDEMICS OF POLIOMYELITIS IN ENGLAND.

WE publish this week two reports of small epidemics of acute poliomyelitis, one of 6 cases in the neighbourhood of Deddington in Oxfordshire, and the other of 8 cases at West Kirby in Cheshire. Both present certain features of interest to which it may be well to direct attention. In the Deddington epidemic, which seems to have followed a somewhat circular route, not unlike what has been observed in one or two of the smaller French epidemics as recorded by Netter, it was apparently impossible to trace any direct contagion, even by the interposition of poliomyelitis carriers, except in 2 cases, and in regard to them the circumstances are not particularly striking. On the other hand, the remark is made that all the cases lived in close proximity to stables. Reference has already been made in the columns of THE LANCET to the experimental work of Anderson and Frost on the transmission of poliomyelitis by means of the stable fly (Stomoxys calcitrans), and it is suggested in connexion with this Deddington epidemic that it originated in infected stomoxys biting the patient whose case is No. 1 in the series. At least one other small epidemic, recorded by Dr. Edwin Bramwell as occurring at Tillicoultry, is known to have been localised in the neighbourhood of farm steadings, and it may well be that these epidemiological facts will serve to throw some light on the spread of the disease in certain localities. At the same time, it must not be forgotten that in the larger epidemics there are innumerable instances of spread of the contagion by totally different methods, and in view of the fact that poliomyelitis is more or less endemic in London it is improbable that its continuance is associated with the presence of the stable fly. However, the interesting features of the Deddington epidemic are worthy of careful consideration. The analogies between the Borna'sche Krankheit of horses and poliomyelitis are, in the present state of our knowledge, scarcely definite enough to lay much stress on. The outbreak of acute poliomyelitis at West Kirby is important inasmuch as the first case occurred last year, in July, as a sporadic or isolated instance of the affection; seven fresh cases occurred in July and August of this year. From what we have learned of the infectivity of the virus and the possibility of its being carried by individuals who do not actually suffer from the disease, there is nothing remarkable in the reawakening of the disease at West Kirby this summer. There is every reason to suppose that the virus lived during the winter in the nasal mucous membrane of one or more individuals related to the primary case. In this epidemic direct infection by contact seems very probable in a number of the cases. Suspicion has fallen on certain vermin—viz., lice—as being perhaps connected with the origin of the disease in the West Kirby series, and where there is still much that is obscure, it behoves the epidemiologist to weigh carefully and without bias the evidence for and against. It has frequently been remarked in connexion with poliomyelitis that domestic animals have been kept in many houses where the disease showed itself. Yet there are just as many instances of the affection in which no association with the presence of domestic pets is demonstrable. Nevertheless, in the West Kirby epidemic the alleged transmission is one to which the attention of those who have the opportunity of experimental investigation will, we trust, be directed. The somewhat curious circumstances surrounding the first appearance of the disease in this district ought not to be forgotten. The documentary value of these two reports is considerable. From small and localised epidemics, as in this Upminster and Tillicoultry instances, much can be learned of significance from the epidemiological viewpoint, and we trust that any other localised groupings of the disease of this summer or autumn will not go unrecorded.

VALLEY FLOODS AND PUBLIC HEALTH.

AN interesting report has recently been presented to the Surrey county council by the consulting medical officer, Dr. Edward C. Seaton, on the Wey Valley Floods in Relation to Public Health. In discussing the influence of floods on health Dr. Seaton remarks that it hardly needs much argument to demonstrate their ill-effect when the dwellings of populous areas are partly submerged, and when the necessaries of life have to be provided for by the help of boats. Even floods of far less magnitude than those which occurred in Nottingham in 1876 and in Norwich last year constitute, he says, not only an acute source of discomfort for the unfortunate residents, but leave behind them the foundation of illnesses of many kinds and often of a chronic nature. Further on he observes that the extent to which ill-health arises is not defined, for there are conditions of the soil which sometimes follow floods and which are liable to become continuing causes of disease. There are, for example, the conditions of the saturation and wetness of the earth upon and near to the surface, which have long been recognised as the underlying causes of illness, either directly or indirectly, sometimes through the medium of insect life. Reference is made to the classical reports of the medical department of the Privy Council upon this subject, and also to a letter written by Dr. R. W. C. Pierce (medical officer of health of Guildford and Woking) to the River Wey Floods Association, in which he drew attention to the remarkable lessons taught by the experiences of the Fen districts of Lincolnshire and Cambridgeshire, where ague was prevalent until a great land drainage system was introduced, when the disease practically disappeared. Instances are also quoted by Dr. Seaton of the salutary effect of building houses above a certain level in districts liable to be flooded by an overflowing river. With these improvements in structure and levels the regional prevalence of phthisis has been lessened. In Leicester, again, the general death-rate has been remarkably reduced since the establishment of a system of drainage which has for some years been held up as a model for other towns similarly situated as regards their levels. Improved drainage is unquestionably an important factor in regard to rendering low-lying places in the neighbourhood of rivers healthy to live in. Much land, says Dr. Seaton, in regions of the valley of the Thames and its tributaries, which is at present uninhabitable, could in time be reclaimed by well-considered comprehensive measures having for their object the unimpeded flow of water right away from its outlet

to the tidal river at Teddington Weir during times of threatened floods in its higher reaches. A well-considered scheme on the lines suggested would, in Dr. Seaton's experience, prove an immense boon to the country generally, including certain parts of Surrey, inasmuch as it would be the means of removing a potent factor in disease. Further, labourers' dwellings should be planned with due regard to health requirements. Dr. Seaton considers that by sufficient drainage of low-lying, damp regions which are at present uninhabitable, these regions would be reclaimed to the public advantage.

THE CONTROL OF MASSAGE AND OTHER ESTABLISHMENTS IN LONDON.

THE Public Control Committee of the London County Council have reported to the Council as to the details of the proposals for the control of massage and similar establishments recently adopted. The subject has been thoroughly discussed in our columns from several aspects.[1] The committee stated that nursing homes were proposed to be included, but added that with regard to the great majority of nursing homes, and many establishments providing the other forms of treatment, there was no suggestion as to their being carried on in any other than a proper manner. It was sometimes alleged that nursing homes were conducted by unqualified persons or with an insufficiently qualified staff; as to this the committee was not in a position to judge. They did not consider it to be the duty of the County Council to interfere in such matters. They felt, however, that the principle of registration was the best one that could be adopted, the right of appeal to a court of summary jurisdiction being given. The report stated that special means must be taken to deal with attempts at evasion by adopting trading descriptions other than those specified by the Council. Furthermore, if the proposed legislation was to be effective severe penalties must, they concluded, be imposed, while all powers obtained ought to be exercised by a central authority. The powers proposed to be acquired by registration are very full. The premises to be registered are to comprise those used as nursing homes or for the purposes of massage or manicure or for administering curative treatment by light, electricity, or baths, or other similar treatment, but all Poor-law institutions, and such hospitals and other premises as may be later defined, are to be exempt from registration. Where the registration authority has reason to believe that the title of a business has been adopted as a cloak to the carrying on of a disorderly house, its officers having a special right of entry, subject to regulations, will proceed to action. The penalties provided are £50 and a daily penalty not exceeding £20 for a first offence, and the same maximum penalties, with or without a term of imprisonment, in respect of a second or subsequent offence. In the case of a company it is provided that proceedings may be taken against all or any of the directors as well as against the company. The committee have also proposed that—

> It shall be an offence for any person or company knowingly to advertise or print or publish an advertisement of any owner or occupier who has been struck off the Register,

a method of action which shows that the source of the evil is properly recognised. The proposals of the Public Control Committee were approved by the Council, and action will follow upon the lines indicated.

[1] THE LANCET, Oct. 18th (p. 1131) and 25th (p. 1206).

THE TRIAL OF BEILISS.

THE Justschinski trial has concluded, with a verdict of acquittal for Beiliss, the Jew accused of murdering a Christian boy for the purpose of obtaining Christian blood for ritual use. A different verdict would have been unthinkable in any civilised country save Russia. But in Russia, and in a leading university town, possessed of all the appurtenances of an advanced civilisation, the barbarous belief that such murders do take place still prevails, and until the very end of the case Beiliss's fate hung in the balance. Indeed, skilled experts seem to have been so affected by the prevailing belief as not to realise that the established medico-legal facts in the case, so far from lending support to the accusation against the accused, failed completely to substantiate any likelihood of a ritual murder. The matter is really brought to a very clear issue in a pamphlet entitled "Der Fall Justschinski,[1] Ofizielle Dokumente und private Gutachten." This pamphlet contains first the following protocols: the post-mortem record of March 2nd, 1911; the second post-mortem record of March 26th, 1912; the report of Professor J. A. Sikorski, of the University of Kieff; Protocol 61, Report of Professor Obolonsky and Prosector Tufanow. The second part consists of the opinions thereon of Professor Haberda, of Vienna; Professor Ziemke, of Kiel; Professor Lacassagne, of Lyons; and Professor Thoinot, of Paris; Mr. A. J. Pepper, Dr. Charles A. Mercier, and Dr. W. H. Willcox, of London; Professor Bleuler, of Zürich; Professor Bonhöffer, of Berlin; Professor Boedeker, of Zehlendorf; Professor A. Forel, of Zürich; Professor Meyer, of Königsberg; and Professors v. Jauregg and Obersteiner, of Vienna. None of these opinions lend any support to the theory of ritual murder put forward with circumstantial detail by Professor Sikorski in a report which is traversed in a lucid and weighty manner. From perusal of this pamphlet it seems to us quite clear that the luckless boy was not killed with any design of securing his blood for any purpose, and was not tortured. The act was probably that of a lunatic.

INACCURACY OF AMERICAN MORTALITY STATISTICS.

A STARTLING article on the inaccuracy of American mortality statistics, written by Dr. Horst Oertel, pathologist to the Russel-Sage Institute of New York, has been sent to us, extracted from a journal called the *American Underwriter*, and its lessons may not unprofitably be taken to heart by some persons in this country who justly fall under Dr. Oertel's censure as dogmatic writers on the statistics of fatal diseases without troubling to test the reliability of the data upon which their statements are founded. "It is strange," says Dr. Oertel, "that, notwithstanding much discussion about improvements in the methods of recording and interpreting these statistics, the reliability of the death certificate itself is generally accepted." He then proceeds to show that the errors and inaccuracies in the present returns of causes of death are so great that it may fairly be doubted whether deductions based on the evidence of American statistics are at all trustworthy. The majority of American

death certificates, even those of the larger hospitals, which represent the best available records, are based mainly on bedside diagnosis only. The testimony of American physicians who have systematically performed necropsies appears to be to the effect that the majority of clinical diagnoses are either wrong or quite insufficient to establish the cause of death. From his own experience Dr. Oertel does not hesitate to state that even at the time of the necropsy the medical man is frequently uncertain about the character of the disease and arrives at the truth only after prolonged study. The statistics of Dr. Cabot, of Boston, are instructive in this regard. He has published the percentages of correct diagnoses of what appeared to be the most important lesions revealed by 3000 necropsies in that city, from which it appears that even in the hands of an experienced diagnostician the diagnosis of certain diseases was proved correct in the case of not more than 25 per cent. of the deaths; whilst the percentage did not exceed 75 per cent. in the case of any other fatal disease in the list. Commenting on Dr. Oertel's paper the editor justly remarks that if the actual causes from any considerable proportion of deaths have been incorrectly diagnosed, and the death certificates made out accordingly, the whole structure of a country's mortality statistics fairly totters, and the grouping of classes, ages, and ratios is necessarily subject to the most serious doubts. It is this gravest of dangers in the compilation of American mortality statistics to which Dr. Oertel directs attention, and, in our judgment, the subject is worthy of the serious attention, not of vital statisticians alone, but of all the more important medical societies, medical colleges, and hospital authorities of the country.

ALFRED RUSSEL WALLACE.

THE death of Dr. Alfred Russel Wallace occurred, at the ripe age of 90, on Friday of last week, Nov. 7th. He will for ever be remembered by his association with the great alteration in all our scientific standpoints brought about by the establishment of the modern doctrines of evolution. As is well known, Wallace enunciated the theory of natural selection at the very time when Darwin, after 20 years of solid work, had arrived at similar conclusions, though after more profound and wide-ranging investigations. The attitude of the two philosophers was marked by the greatest generosity to each other; and when the world elected, and elected quite rightly, to give to Darwin the chief credit, Wallace's acknowledgment of the justice of the verdict was complete. The statement that has been made in many places lately that the work of Wallace was put aside and that he himself was unduly neglected does not bear investigation. He was not a candidate for the Fellowship of the Royal Society until quite late in his career, but that body elected him as soon as the usual formalities were complied with, and he was the recipient of one of their most important medals. Wallace was an individual and romantic thinker, but his intuition did not always serve him as well in his attempts to solve other problems as it had when he had jumped at the correct explanation of the processes and changes in organic life. Some of his writings, while they displayed independent judgment, were not marked by the discrimination that might have been expected from so famous a man, and his attitude towards one phase of scientific medicine was unfortunate. But it would be wrong to be blind to the value of grand receptive intelligences like his, because in one or two points the conclusion which Wallace came to appears to us to be hasty. Medicine combines with the scientific world in deploring the loss of a leader, and in acknowledging the debt of the world to a pioneer in the interpretation of the universe.

OCTOBER AT HOME AND ABROAD.

OCTOBER was a very mild month, with a succession of winds from the south and south-west, bringing abundant rain, but occasional clear skies, which allowed the sun to shine for about the average number of hours for the month. October is normally the wettest month of the year in nearly all parts of this country, and generally gives at least one bad wind storm. On this occasion, however, the cyclonic systems either remained on the Atlantic or became reduced in energy on arriving over these islands, and except on some of the most exposed points of the western and northern coasts the wind seldom rose to the strength of a gale. On the ocean to the west a vast area was frequently in a very disturbed condition, some of the storms being very severe, and continuing for days. In England the thermometer was often 5° or 6° above the normal level both during the day and at night, and sometimes the divergence was greater, but as there were a few relatively cool spells, the mean for the whole period was no more than 3° or 4° above the average. At Kew, where the maximum temperature was as high as 60° or higher on 17 afternoons, the mean, 60°, exceeded the average by 4°, while the mean minimum of the night, 46°, was 3° above. At Bath, Torquay, Bournemouth, and Brighton the mean maximum was 61°, and the mean minimum also higher than at Kew, except at Bath. At Torquay and Brighton the figure was 51°, and at Bournemouth 48°. In the Midlands the mean maximum temperature was a little below 60°, and in the north of England, as represented by Harrogate and Buxton, 54°, and the mean minimum 44° or 43°. Paris was warmer than the mainland of this country during the day, recording a mean maximum of 62°, the same figure as Jersey, but at night it was colder, the mean minimum being 45°, no higher than that at Bath. At Brussels the corresponding figures were 61° and 46°, but at Berlin they were lower, the mean maximum of the day only reaching 57°, and the mean minimum of the night being as low as 42°. Over the southern regions of Europe there were few days with a lower temperature than 70°, while in southern Italy the thermometer occasionally exceeded 80°. Round about the 23rd the sheltered thermometer fell to a little below the freezing point in the Midlands and north of England, and to some degrees below it in central Ireland, but no frost was registered at Paris or Brussels, and only one, on the 26th, at Berlin. In most parts of this country there was more or less rain on at least 18 days. In the metropolitan area the total fall was about 3·5 in., exceeding the average by about 0·75 in. Bath had rather less rain, its total of 3·1 in. only exceeding the average by 0·05 in., while at Harrogate there was no more than 2·8 in. against an average half an inch greater. Along the south and south-west coasts there was, as a rule, more rain than in London. At Brighton, where as many as 20 days furnished a measurable amount, the aggregate was 4·2 in., a figure 0·7 in. more than the normal. At Bournemouth it was 3·4 in., at Torquay 3·7 in., or 0·4 in. less than

the normal, and at Newquay 5·0 in., or 1·2 in. more than the normal. In the Midlands the fall generally exceeded the average, although in some localities rain was less frequent than in the south and south-west. At Nottingham there were no more than 14 days with rain, against 20 in Brighton and Torquay, but the total fall, 3·64 in., was an inch above the normal. At Buxton, where an average October gives 5·4 in., last month yielded no more than 4·6 in. On the Continent the weather was generally much less rainy than in this country. At Berlin the total fall was 0·6 in., at Brussels 1·4 in., and at Paris 1·8 in. In the southern countries there were a few heavy local falls, but the general character of the weather was dry and bright. In these islands it is now far too late for the total duration of sunshine for the year to equal the average, but last month did its best here and there to make up the deficit, although its best was not very striking. At Kew the total number of hours of bright sunshine was 97, an excess of only 3 hours on the average, but in many places the deficit grew even larger than at the end of September. At Brighton the total of 114 hours was 3 hours less than the normal, and in the Midlands and north of England the weather was mostly less bright than usual. At Nottingham the total sunshine, 76 hours, was 17 below the normal, and at Harrogate, where the figure was 67 hours, it was 28 hours less. On the extreme south-western coast the sky cleared more frequently. At Torquay the sun shone for 113 hours, about the average figure, and at Newquay for 122 hours, an excess of 11 hours on the average. Jersey was brighter than any place farther north, having the good total of 147 hours against an average of 127 hours. Absolutely sunless days were not often experienced in any part of the kingdom. At Kew there were only 4, and in the Midlands 6, 7, or 8, while on the south coast there were only 2 or 3, and at Newquay not one. At Jersey, however, there were 3 sunless days. At Kew the brightest day was the 31st, when the sun shone during seven hours, but over the kingdom generally the maximum amount of sunshine was recorded on various dates—mostly after the 15th. Some places on the south and south-west coasts had between 8 and 9 hours on one day, and a few between 9 and 10 hours. Compared with the south and south-west of these islands and Jersey, Paris was dull. On 5 days the sky was overcast throughout, and the aggregate amount of sunshine for the month was no more than 106 hours, or 41 hours less than at Jersey and 16 less than at Newquay.

THE ANTHRAX COMMITTEE.

AN opportune announcement was made at the close of last week by the Home Secretary that he has appointed a committee of nine to inquire into the dangers from infection by anthrax in the various processes incidental to the wool and hair industry, and to consider and report upon any amendments to the existing regulations which may be desirable. The chairman is Sir Thomas Whittaker, M.P., and the committee contains representatives of the more important interests affected, such as the Bradford Chamber of Commerce, the Bradford Trades and Labour Council, the National Union of Woolsorters, and the Bradford and District Wool Top and Noil Warehousemen's Union. The medical and scientific representation although small, is extremely efficient. It is certain that with Professor F. W. Eurich, of Leeds University, and Dr. T. M. Legge, of the Home Office, upon the committee this side of the inquiry will receive full attention. Professor Eurich, as bacteriologist to the Bradford Anthrax Investigation Board and specialist medical referee to the Home Office for anthrax, has identified himself with the subject under investigation; while Dr. Legge, as one of His Majesty's medical inspectors of factories, has exceptional experience of industrial diseases, and chose as the subject of his Milroy lecture before the Royal College of Physicians of London, in 1905, Industrial Anthrax and Serum Treatment. The secretary to the committee is Mr. G. E. Duckering, of the Home Office, and communications relating to the subject of the inquiry may be addressed to him at 72, Bridge-street, Manchester.

LARGE AMOUNT OF UREA IN THE PERICARDIAL EFFUSION IN BRIGHT'S DISEASE.

THOUGH pericarditis is a well-recognised complication of Bright's disease, the connexion between the two is still disputed. Some writers attribute the pericarditis to toxæmia; others to a superadded infection, usually to a pneumococcic one. In a recent thesis M. André Weill has given the results of the examination of 11 cases. In 2 there was less than 2 grammes of urea in the pericardial fluid, in 6 there were between 2 and 3 grammes, and in 3 more than 3 grammes. Bacteriological examination gave the following results. In 4 cases it was negative; in 2 colonies of the colon bacillus were obtained but the organism was not agglutinated by serum obtained from the patient during life—evidently the infection was agonal; in 1 case there was found a streptococcus and in 4 cases the pneumococcus. At a meeting of the Société Médicale des Hôpitaux of Paris on Oct. 24th M. E. de Massary and M. P. Chatelin reported the following case. A woman, aged 33 years, was admitted into hospital on March 3rd, 1913, complaining of general weakness, cramps in the lower limbs for two months, and dyspnœa. She said she had never previously been ill and had five healthy children. However, two premature labours occurred in 1912, the second at three months on Dec. 27th. Since the end of October she felt fatigued and suffered from pains in the calves and thighs and lost appetite. The miscarriage accentuated this condition. In January, 1913, the legs became a little swollen and the urine was examined and found to contain a large quantity of albumin. She was put on a milk diet but she did not improve, vomiting occurred four or five times a week, and she lost flesh. On examination she was thin, sallow, and pale. The respiration was shallow and irregular (20 to 22 per minute). There was a little œdema, localised exclusively behind the malleoli. The liver was enlarged, and there was a history of alcoholism. At the outer base of the left lung there was slight dulness and crepitation was heard. Some thick mucus was expectorated. The cardiac dulness was enlarged transversely and the apex beat was in the seventh space. A little above it a thrill was felt. At two foci—in the fourth and fifth left intercostal spaces and in the second left intercostal space—marked friction was heard in the form of a rough double sound, which was not transmitted to other parts of the chest and did not exactly coincide with the cardiac pulsations. The pulse was 100, strong, and a little irregular. The urine contained 8·64 grammes of urea and 6·25 grammes of albumin per litre; 500 grammes were passed daily. The arterial tension was 22/14 with Pachon's instrument. The blood serum contained 4·2 grammes

of urea per litre. From March 11th to 15th the amount of urine in the 24 hours fell to 300–350 grammes, and the patient vomited and could retain nothing on her stomach. Exploratory puncture at the left base yielded serous fluid. She became somnolent and at times the right eye showed external strabismus. The breath developed an ammoniacal odour. The pericardial friction diminished, but the dulness remained about the same. On March 22nd general convulsions occurred, lasting 10 minutes, during which urine escaped. In the evening she became comatose. Death occurred on the following morning. Soon afterwards 40 to 50 grammes of hæmorrhagic fluid were withdrawn with antiseptic precautions from the pericardium. It contained numerous red corpuscles, some white ones, and patches of desquamated cells. Examination of a film obtained after centrifuging and staining with phenolised thionin did not show any microbes. Also a culture on the serum of the rabbit was negative, as was also inoculation of a mouse. The pericardial fluid contained 6·4 grammes of urea per litre. At the necropsy 90 grammes of hæmorrhagic fluid was found in the pericardium, on which there was a fibrinous deposit. The kidneys were granular and much atrophied; the right weighed 80 and the left 40 grammes. The liver weighed 1300 grammes and was soft and fatty. The lungs were œdematous, and at the left base the tissue was a little more dense and was congested. Sections of the pericardium were examined microscopically for microbes without result. Evidently the pericarditis was due to retention of urea in the system and its accumulation in the pericardium.

ACUTE TYPHLITIS.

SINCE the discovery of appendicitis the term typhlitis has almost disappeared from medical literature, and it is generally held that the cases described by the older writers under this designation were examples of appendicitis. That they were not entirely wrong is shown by the following case of primary acute typhlitis reported in the *Australian Medical Journal* of Sept. 27th by Dr. Geoffrey Owen, who also refers to a very similar case previously recorded in the same journal. He was urgently summoned to a woman, aged 25 years, who had been well till two days previously, when she was seized with abdominal pain and vomiting. At first the pain was referred to the middle of the abdomen, but after 24 hours it became localised in the right lower quadrant. At the end of 12 hours the vomiting ceased. There was no history of previous illness except slight anæmia. On examination she did not look ill. The temperature was 99·2° F., the pulse 88, and the tongue clean. Abdominal respiration was good, but there were definite tenderness and rigidity in the right lower abdomen. The bowels had acted after the administration of castor oil. Acute appendicitis was diagnosed, and though there were no urgent symptoms an operation was advised and was performed next morning. Slightly turbid fluid was found in the peritoneal cavity. Immediately under the peritoneum a mass of omentum was encountered, and on attempting to unravel this it was found to be intimately connected with the bowel and the incision had to be considerably enlarged to make out the condition. The cæcum and part of the ascending colon were found surrounded with omentum, which was glued to them by recent delicate adhesions. The condition of the bowel was remarkable. The cæcum was studded all over with injected vessels, which extended well up the ascending colon. The appendix lay tucked behind the cæcum and was not nearly so injected as the colon. It presented no other sign of disease. The omentum which was wrapped round the large bowel also presented the same curious appearance of acute injection, and in addition was very friable, tearing on the least touch to separate the adhesions. Its terminal part formed œdematous masses. This looked so rotten that it was deemed advisable to ligature off and remove several large pieces. The appendix was removed in the usual manner. Recovery was uneventful. Dr. Owen concludes that the case was one of primary acute typhlitis in which the appendix was only involved in the general process and was not the primary seat of the disease.

MEDICAL TRANSPORT WITH NAVIES.

THE October number of the *Military Surgeon*, an interesting Chicago publication, is mainly filled with articles on the management of the wounded in naval actions. Director-General C. F. Stokes, of the United States Navy, has worked up a scheme which details a "medical transport," a ship of 10,000 tons or more, to each division of the fleet, a division including four battleships with destroyers and auxiliaries. After a battle the medical transport arrives and sends to each of its battleships, or to its destroyers, a section of its boats with a dozen medical officers and sick-berth stewards and four dozen sick-berth attendants. They all get on board the battleship of whatever sort it may be, give what additional attention is required to the wounded, and move these into the boats and take them to the medical transport for conveyance to the base. This scheme was obviously suggested by the field ambulances or bearer companies of the army. It is too elaborate to be of use at sea. In bad weather Director-General Stokes proposes to transfer wounded in cots along an aerial railway, sliding the cots on a wire hawser stretched from the stern of their ship to the bow of the medical transport. A similar method was tried in our navy for coaling ships at sea, but did not give satisfaction. The first essential for the satisfactory care of the wounded in a naval action—namely, that their fleet must be brought out victorious—is forgotten. Extemporised measures will secure a higher percentage of recoveries for the victors than the most elaborately prepared plans can hope to achieve for the vanquished. So it is a serious matter to propose to make arrangements to help the wounded which shall in any way hamper the fighting efficiency of their ship or squadron. Surgeon J. L. Pleadwell's paper on the Relationship of the Hospital Ship to the Fleet in Time of War is most instructive in this connexion. The problems of the medical officer in charge, although so tangled, are very clearly stated and resolved. This thoughtful article should be read by every naval medical officer. A similar remark applies to Captain Lazell's paper on Mental Hygiene, and the improvement of the rank and file in army and navy. The Association of Military Surgeons of the United States, including Army, Navy, and Public Health Services, held its annual meeting at Denver, Colorado, in September, under the presidency of (Fleet) Surgeon W. C. Braisted, United States Navy; and Surgeon-General W. H. Norman, representing the Royal Navy and

Royal Army Medical Services, received a hearty welcome.

A LANTERN lecture will be delivered before the Fellows of the Royal Society of Medicine, in the Robert Barnes Hall, 1, Wimpole-street, on Thursday, Nov. 20th, at 5 o'clock, entitled "The Leprosy Problem in the British Empire, illustrating the Clinical and Bacteriological Aspects of the Disease: with Remarks on the Clinical Aspects of Syphilis among Natives," by Dr. H. Bayon, Research Bacteriologist to the Government of the Union of South Africa.

MEDICINE AND THE LAW.

A Death Certificate Given by an Unqualified Person.

AT the recent Gloucester assizes a prisoner charged under the name of Jose Manuel de Freitas was indicted for having given a certificate of the cause of death not being a medical practitioner, for fraudulent conversion of money entrusted to him for the purchase of surgical instruments by the Cinderford and District Friendly and Medical Aid Association, and also for having obtained £37 by false pretences from the association. It was stated that the prisoner, who pleaded guilty, obtained the post of medical officer of the association mentioned by replying to an advertisement, and carried out his duties for three weeks without complaint from his patients. The association is not to be congratulated upon the success of its efforts to obtain a medical attendant for its members, and it would be interesting to know what steps it took to ascertain the qualifications of the man whom it engaged; for the prisoner, in addition to the fact of his not being a medical practitioner, although he bore, or had assumed, the surname of a gentleman on the Register, was given a very bad character by a detective from Scotland Yard. He was described as a man who lived by fraud and on the immoral earnings of women; he had defrauded a lady of over £1300 and a gentleman of £100, and had also carried on unqualified practice in several localities. He was sentenced by Mr. Justice Coleridge to 10 months' hard labour, which does not seem an excessive penalty.

An Attempt to Blackmail a Medical Man.

At the recent sessions of the Central Criminal Court a man named Gates, a picture framer, 21 years of age, was convicted and sentenced to three years' penal servitude upon an indictment charging him with sending to Dr. W. J. Bell a letter demanding money from him with menaces and without any reasonable or probable cause. The prosecutor, a medical man practising at Peckham, and being upon the panel under the Insurance Acts, attended a girl named Wright at his surgery, where he saw her on four occasions, and afterwards at her father's house, where she was in bed under his orders, and where he paid her six visits. This was before April 28th, after which date and before July 31st the patient paid 23 visits to the prosecutor's surgery. Early in August the prisoner had banns of marriage between himself and Wright published at a local church and fixed the marriage for August 25th. On August 12th a letter was received by Dr. Bell accusing him of improper conduct towards Wright, and threatening that an action claiming £2000 damages would be started unless a settlement by payment of £100 should be made. Dr. Bell wisely took the only right course with promptitude, communicating immediately with his solicitors, and the police arrested Gates and Wright. The latter pleaded guilty, and stated through counsel that she in fact wrote the letter, but that Gates was responsible for the whole of its contents, that there was not a particle of truth in the allegations made in it, but that every suggestion in it came from Gates who had coerced her into copying the document. She was bound over to come up for judgment when called upon. Dr. Bell is to be congratulated upon the conclusion of an episode which must have been a very painful one to him, and upon the successful and complete repudiation of an odious charge which exemplifies the dangers to which the medical practitioner is frequently exposed in the exercise of his profession. It may be mentioned that in his opening speech, after describing the number of attendances required by the illness of Wright (who had suffered from rheumatism), Mr. Bodkin, who appeared for the prosecution, called attention to the thoroughness of the treatment accorded to her under the Insurance Acts.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Treatment of Tuberculosis.

FOR four hours on Nov. 4th the Council debated the Public Health Committee's reports which appeared in THE LANCET of Oct. 25th, p. 1205, and Nov. 8th, p. 1332, with regard to provision for uninsured persons suffering from tuberculosis. Discussion first took place with regard to the recommendation, already published in full, as to the financial basis of the provision for treatment of uninsured persons.

After some debate on the general question, in the course of which it was pointed out that the formulation of a comprehensive scheme for London had been under consideration by the Council ever since the Insurance Act was passed in December, 1911, the following motion was proposed by Mr. RAWSON:—

That the recommendation be referred back to the committee with instructions to ascertain whether the metropolitan borough councils desire local dispensaries to be under the sole control of the borough councils or the London County Council.

An amendment that steps be taken to arrange another conference with the Local Government Board was lost by 45 votes to 32, and the original motion was then put to the vote and defeated.

Dispensary Provision for Uninsured Persons.

Mr. A. L. LEON moved an amendment to the Public Health Committee's recommendation in the following terms:—

That the Council, whilst regretting that a scheme has not been made earlier, is of opinion that no scheme for the treatment of tuberculosis in London can be comprehensive or satisfactory while the Council is prevented from dealing with the provision of dispensaries by the premature action of the Local Government Board in approving partial and local schemes in London, and that the Board be asked to cancel all consents given for the erection of dispensaries, and to make an Order enabling the Council itself to provide and administer (itself or through borough councils) all dispensaries required, one-half of the expense to be defrayed out of the county fund as expenditure incurred for general county purposes and one-half to be defrayed by the Government.

Mr. Leon advised the Council, since the Local

Government Board had taken a line which deprived the Council of authority, to wash its hands of dispensaries schemes and confine itself to the provision of sanatoriums. It was a matter for keen regret that the Local Government Board should have allowed a number of dispensaries to be started in different parts of the metropolis without regard to the needs of London as a whole. It would be impossible to coördinate and make available the highest medical skill and knowledge existing if the borough councils were to be the units for dealing with the tuberculosis question. The Public Health Committee had conferred with the authorities of 12 large hospitals; these bodies were very anxious to fall in with a scheme, but they made it an essential that the Council should be the one centralising authority for London. In some boroughs there were no hospitals, and there were cases where a borough council had refused to act with a hospital and *vice versâ*.

Mr. F. BRIANT, who seconded, said he did not wish to be unduly severe on the borough councils, but no more serious blow could be struck at a comprehensive policy than to leave hospitals out of a tuberculosis scheme. The hospitals with medical schools—in fact, the whole of the teaching hospitals—had passed a resolution in which they had emphasised the importance of the administration being in the hands of the London County Council. If the borough councils declined to have anything to do with the hospitals very unsatisfactory results would be obtained. Of 730 people treated at St. Thomas's Hospital dispensary 340 required special surgical treatment, and this was not available at an ordinary tuberculosis dispensary.

Mr. J. A. DAWES, M.P., Chairman of the London Insurance Committee, said that the time for moving the amendment had passed; six months ago it might have been acceptable. The Council ought to have been in possession of the views of the Local Government Board at a much earlier date; the Board had taken a most unfortunate line. Rather than have any more delay the Council had better pass this scheme and try to induce the borough councils to adopt some suitable measures for their respective areas. Nothing could be more unfortunate than to have 29 areas each in a ring fence, but that was what matters had come to. He did not think the hospitals made it an essential condition that the County Council should be the authority; they would try to make the best of a bad job. He did not like this scheme, but in the interests of tuberculous persons it should be adopted. The County Council was still the authority for residential purposes, and this might give it some power; the monetary control was just worth having.

Mr. O. E. WARBURG hoped that it would be possible to secure the coöperation of the hospitals, and that the County Council would be able to maintain a proper balance between dispensaries, hospitals, and local medical officers of health.

The amendment was lost by 34 votes to 20.

Financial Questions.

Debate then took place on the question of equalising the cost of tuberculosis treatment throughout the metropolis so that boroughs where the phthisis rate was high and was accompanied, as would usually be the case, by a low rateable value should receive financial assistance. Amendments to secure this were defeated by considerable majorities.

Mr. GILBERT JOHNSTONE moved an amendment that in view of the fact that the London Insurance Committee had resolved to make representations to the Treasury as to the inadequacy of the sums available for sanatorium benefit in respect of insured persons the Council was of the opinion that no comprehensive scheme could be carried out adequately unless provision were made for meeting the full cost of the treatment of insured persons out of the Insurance Fund or by the Government.

Mr. DAWES pointed out that the only deficit as to which the Insurance Committee made representations was in respect of residential treatment, and the shortage was due to the fact that the British Medical Association had been able to secure the allocation of 6*d.* per head to the doctors for domiciliary treatment. There were sufficient funds to provide for dispensary treatment.

The amendment was carried by 42 votes to 22.

The recommendation as amended was then agreed to in the following form:—

That any comprehensive scheme for dealing with the treatment of tuberculosis in London shall provide for a contribution being made by the Council from year to year towards so much of the cost of the dispensary treatment of uninsured persons in the City of London and each metropolitan borough as would otherwise fall on the local rate, after taking into account the promised grant from the Imperial exchequer, provided that such contribution (1) shall not exceed 50 per cent. of such cost; (2) shall be made in the first instance from a date to be fixed hereafter by the Council; and (3) shall be conditional upon the Council being satisfied with the local scheme in force in such area and upon the arrangements and the expenditure being annually submitted to and approved by the Council. Whilst by the above proposals ample funds will be provided to meet the cost of dispensary treatment for uninsured persons, in view of the fact that the London Insurance Committee has resolved that representations shall be made to the Treasury as to the inadequacy of the sums available for defraying the expenses of sanatorium benefit in respect of insured persons suffering from tuberculosis in the county of London, the Council is of opinion that no comprehensive scheme can be carried out adequately unless provision is made for meeting the full cost of the treatment of insured persons out of the Insurance Fund or by the Government.

Residential Accommodation for Uninsured Persons.

On the report of the Public Health Committee with regard to residential accommodation for uninsured persons and its recommendation that the Council should make arrangements with the Metropolitan Asylums Board, with hospitals and with sanatoriums without the Council owning or managing institutions (see THE LANCET, Nov. 8th, p. 1332).

Major LEVITA moved an amendment to the effect that the Council should not act as a financial intermediary, but should leave it to local health authorities, the Asylums Board, and other bodies to deal with tuberculosis. He criticised the proposed arrangements on the ground that at every stage of the disease except one the borough councils were to deal with tuberculosis; the County Council which had lost control of the scheme as a whole was to come in and deal with one small section of the problem. It would be irritating to the hospitals to find that as long as a man went to a dispensary he was under one set of authorities, but when the disease needed sanatorium treatment he came under another set of authorities. He did not know that the borough councils, which were the proper authorities to deal with health matters, had asked the County Council to make arrangements for residential treatment. It was estimated that 400 beds were required for uninsured persons; the

hospitals were not full, and he was not sure that existing institutions could not deal with residential treatment now that the Council at the request of the Insurance Committee had provided for insured persons.

The amendment was lost, only five voting in favour.

The debate continued on the main question on the line that the County Council should not delegate to the Asylums Board the provision of accommodation. Mr. DAWES said that although the Asylums Board had done its best to help the Insurance Committee out of a serious difficulty, the institutions it had provided were not entirely suitable, because it had none of the smaller sanatoriums required. As a matter of fact, the Asylums Board had no more institutions suitable for dealing with tuberculosis than had the County Council.

The committee's recommendation was then agreed to.

The Mount Vernon Hospital, Hampstead.

In regard to the views of the London Insurance Committee and of the Public Health Committee as to the acquisition of this institution (see last issue, p. 1333), Mr. L. COURTAULD, a medical member of the Council, moved an amendment to omit an expression of opinion in favour of the purchase of the institution or a communication to the Asylums Board on the subject so that the motion would read:—

That the Council is not prepared to purchase the Mount Vernon Hospital, Hampstead.

Mr. Courtauld said the institution was not suitable for any other purpose than hospital treatment of tuberculosis, and it would be unwise, if not impossible, for the Council to enter upon the conduct of a hospital. The institution was unsuited for a sanatorium because it had only 2½ acres of ground and so did not provide opportunities for graduated exercise and labour. It would be too miserable and depressing a place to be used as a home for advanced cases; these should be put in small cottage hospitals rather than in a big institution in which it would be difficult to persuade them to stay. As to the use of Mount Vernon for hospital cases, this would be undesirable because when things had settled down it would probably be found that there was sufficient provision in London for hospital patients. There were vacancies for male patients in the wards of Brompton Hospital, a thing that had not happened for a very long time. The majority of the large teaching hospitals were willing and even anxious to extend the accommodation in their wards for hospital cases. They feared losing material for teaching. The hospitals were the obvious places to which these cases should go, and it was not incumbent on the County Council either to acquire or advise any other body to acquire such an institution as Mount Vernon for the reception of hospital patients. These were difficult and complicated cases requiring special forms of diagnosis and treatment such as could not be obtained in the ordinary sanatorium but only in the large special fully equipped hospitals. It was one thing for the Council to manage a sanatorium which only required a medical superintendent and one or two assistants, but quite another thing to run a special hospital requiring a specialist staff and a large specialist organisation which the Council would have very great difficulty in bringing together, at any rate until municipalisation or nationalisation of hospitals was very much nearer.

Mr. DAWES said that the London Insurance Committee was favoured by having seven medical members who unanimously urged on a deputation to the Public Health Committee that Mount Vernon should be retained as a hospital to accommodate certain classes of cases. With all respect, their opinion should carry more weight than the single opinion of Mr. Courtauld. That large and influential body of medical opinion was very strongly in favour of the acquisition of Mount Vernon. This was one of the four specialist hospitals of London and if it were closed there would be a shortage of accommodation. The Insurance Committee thought this building would be specially valuable because it would be easy for friends to visit patients there.

The amendment was carried by 52 votes to 30, and the recommendation of the Public Health Committee as amended was then approved.

Administration of the Mental Deficiency Act.

The Council debated at considerable length a proposal by the General Purposes Committee that for the purpose of administering the Mental Deficiency Act, 1913, the Asylums Committee be abolished as a statutory committee, and that a new committee be appointed to coördinate the asylums work and the care of the mentally defective under one administration. Persons having special knowledge and experience of the care of defectives would be coöpted, and the Council would have direct control of expenditure, which it has not at present in the case of the Asylums Committee. Members of the Asylums Committee, without distinction of party, protested against the proposal. Several amendments aiming at postponement having been rejected the Council decided by 69 votes to 48 to proceed with the scheme.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Coventry.—The annual reports of medical officers of health are often used to express the individual views of their authors on administrative and scientific questions relating to public health, and this feature adds much value to an annual report. It is, however, sometimes prudent to recollect that these reports are made in the first instance for the guidance of local administrative bodies, the members of which may take statements of opinion without the reservations which those with technical knowledge would naturally apply. We are led to these observations by perusal of the pages of Dr. E. H. Snell's report for 1912 which discuss hospital provision for cases of infectious disease. We meet there the statement in regard to small-pox "that by experience we have learnt that small-pox is, *par excellence*, the disease which can be entirely controlled by isolation and disinfection." Dr. Snell presumably takes vaccination for granted when he makes no mention of it, but it would be better to explain to the layman that the truth of his proposition rests on the necessity of protection by vaccination, or by previous small-pox, of the staff of the hospital, the disinfecting staff, and the contacts of the patient. On the other hand, in referring to plague, Dr. Snell states that "the mere isolation of the patient and disinfection of premises can only be a secondary means of combating infection; the extermination of the rat is the real desideratum." This is an arguable opinion, but when human plague has been introduced into this country, as has now happened on several occasions, it has not necessarily been rat-borne, and in the suppression of human plague, should it occur in an English city like Coventry, primary reliance ought to be placed on isolation of the human case and not on attempts to destroy rats. The portion of the report to which we refer sets out with some force objections

to "older empirical methods" of isolation and disinfection, and represents that in view of recent research their use must be directed by an intelligent knowledge of individual diseases. This unimpeachable proposition has always lain at the root of epidemiology, a science which is not quite as new as might be inferred from the context of the report. In consequence of the occurrence of some serious cases of ophthalmia neonatorum in Coventry, Dr. Snell, after consultation with Dr. T. Harrison Butler, now endeavours to secure that newly born children, whether they show signs of eye inflammation or not, should have their eyes treated with a 5 per cent. solution of protargol. All practising midwives have been circularised on the subject, and informed that the solution can be obtained from any chemist at a cost of a few pence per ounce. Dr. Snell has reason to think that most of the midwives now adopt this procedure.

Metropolitan Borough of Poplar.—Mr. F. W. Alexander's report illustrates the great variety of useful public work done by his department in this large area of Eastern London. In Poplar great use is made, for disinfecting purposes, of "electrolytic fluid" produced by the electrolysis of a saturated solution of magnesium chloride, to which salt and caustic soda have been added. The cost of production in Poplar is just under £2 per 1000 gallons, and the fluid is used for all ordinary purposes of fluid disinfection, including the cleansing of school premises, and, by a special contrivance, for the treatment of the water in the public swimming baths. The effective and cheap purification of swimming bath water is a most desirable practice. It is said to be adopted in Poplar not with the idea of rendering periodic changes of the water unnecessary, but to keep the bath water fresh and free from harmful organisms all the time it is in use.[1] Mr. Alexander claims, with the support of a committee on the purification of swimming baths which was appointed by the Royal Sanitary Institute, that by supplying one part of free chlorine to every 2 or 3 million parts of water, "not only is the water sterilised or deprived of all organised living molecules, but it is kept sweet and free from odour, and there is no tendency in the water to the deposition of slimy sediments on the floor of the pond." A certain amount of slimy matter collects on the water, but this is readily removed with a swab by the attendant. The "cleansing" of verminous persons is a matter which is often too little considered; there are few operations more useful, and it is satisfactory to find that the borough cleansing station was utilised for over 300 inmates of common lodging-houses in 1912. Some of these came from common lodging-houses outside the borough, the London County Council having arranged for a payment to the borough of 1*s.* per person in such cases. Mr. Alexander publishes a letter from the Local Government Board on the subject of notification of ophthalmia neonatorum, which makes it clear that the official recognition of this term is not limited to purulent ophthalmia caused by the gonococcus, but includes all cases of purulent eye discharge caused by other organisms, when these discharges occur during the first few days after birth. An important prosecution under Section 47 of the Public Health (London) Act took place during the year, which resulted in a decision which overruled a defence that a limited company is immune from prosecution for selling unsound food or exposing it for sale. The decision, however, was on other grounds given against the borough council, which brought the action, not against the retailer of unsound goods, who had surrendered them to the sanitary authority, but against the wholesale dealer from whom the unsound goods had been obtained. The borough council has made representations to the Local Government Board urging that the Public Health Acts should be amended so as to protect the public against the sale of unsound food by wholesale vendors.

Borough of Macclesfield.—In this industrial town, which has a population of about 35,000, and in 1912 a birth-rate of 20·1 per 1000, the rate of infantile mortality is usually high, and last year represented 115 per 1000 births. 37 per cent. of these infantile deaths were attributed to prematurity and congenital debility and defects, and Mr. J. H Marsh states that the majority of the mothers of these infants had previously had abortions, miscarriages, or premature births, and that about half of them suffered from marked ill-health and poor physique. He considers that further reduction in the infantile mortality rate requires to be made by means of much greater future attention to ante-natal conditions, especially those of underfeeding and overwork. Cleanly surroundings of working-class homes, it is well known, have a marked effect on the epidemic diarrhœa of infants, and in this relation Mr. Marsh gives a useful caution against the conclusion that the replacement of outside privy-ashpits by water-closets is all that is required. The dry dust in such cases is often put into portable bins, with loose covers or none, which are left standing in the backyard, overfull and spilling their contents. Often scavengers cannot get on to the premises at the time of their regular visit, and thus the accumulations are increased. Mr. Marsh's demand that dustbins in the centre of the town should be emptied at least twice a week in the summer months and not less than once a week during the rest of the year seems in no way excessive. Although a high degree of fly prevalence is not necessarily accompanied by a high diarrhœal fatality, there are very strong grounds for associating the two occurrences, and high diarrhœa rates would hardly be surprising in the neighbourhood of some of the large uncovered middens of horse manure in the centre of the town, which Mr. Marsh describes as forming a prolific breeding-ground for these carriers of filth into the homes and food of the people.

[1] THE LANCET, March 15th, 1913, p. 770.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8687 births and 4561 deaths were registered during the week ended Saturday, Nov. 8th. The annual rate of mortality in these towns, which had been 13·6, 13·1, and 13·9 per 1000 in the three preceding weeks, declined to 13·3 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 13·6 per 1000, which was equal to the rate recorded in London during the same period. Among the several towns the death-rate last week ranged from 4·8 in Gillingham, 6·8 in Oxford, 7·6 in Willesden, 7·7 in Newport (Mon.), and 7·9 in Aberdare, to 18·8 in Middlesbrough, 18·9 in Stockton-on-Tees, 20·1 in Great Yarmouth, 20·2 in Dudley, and 21·6 in Barnsley.

The 4561 deaths from all causes were 193 fewer than the number in the previous week, and included 435 which were referred to the principal epidemic diseases, against numbers declining from 925 to 509 in the four preceding weeks. Of these 435 deaths, 261 resulted from infantile diarrhœal diseases, 46 from whooping-cough, 46 from diphtheria, 34 from scarlet fever, 30 from measles, and 18 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3, against 1·6 and 1·5 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily decreased from 769 to 322 in the four preceding weeks, further declined to 261 last week; of this number 68 were registered in London, 16 in Manchester, 12 in Liverpool, 10 in Birmingham, 9 in Stoke-on-Trent, and 8 in Sheffield. The deaths referred to whooping-cough, which had been 32, 27, and 45 in the three preceding weeks, were 46 last week, and included 11 in London, 5 in Liverpool, 4 in Manchester, and 3 in Birmingham. The fatal cases of diphtheria, which had been 49, 38, and 51 in the three preceding weeks, fell to 46 last week; 5 deaths occurred in London, 4 in Leeds, 3 in Birmingham, and 2 each in Edmonton, Grimsby, Bolton, and Rhondda. The deaths attributed to scarlet fever, which had been 16, 24, and 24 in the three preceding weeks, further rose to 34 last week, and included 6 in Salford, 3 in Warrington, 3 in Sheffield, and 2 each in Birmingham, Liverpool, and Manchester. The deaths referred to measles, which had been 25, 27, and 49 in the three preceding weeks, declined to 30 last week; 6 deaths were registered in Liverpool, 3 in London, 3 in Stoke-on-Trent, 3 in Sheffield, and 2 each in Norwich, Birmingham, and Stockport. The fatal cases of enteric fever, which had been 20, 13, and 18 in the three preceding weeks, were again 18 last week, and included 3 in London,

3 in Wigan, and 2 each in Portsmouth, Bristol, and Rhondda. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily risen from 2112 to 3580 in the nine preceding weeks, had further increased to 3731 on Saturday last; 619 new cases were admitted during the week, against 575, 530, and 534 in the three preceding weeks. These hospitals also contained on Saturday last 1192 cases of diphtheria, 167 of whooping-cough, 80 of enteric fever, and 60 of measles, but not one of small-pox. The 1126 deaths from all causes in London were 104 fewer than the number in the previous week, and were equal to an annual death-rate of 13·0 per 1000. The deaths referred to diseases of the respiratory system, which had been 151, 178, and 207 in the three preceding weeks, slightly declined to 205 last week, and were 21 below the number recorded in the corresponding week of last year.

Of the 4561 deaths from all causes in the 96 towns, 176 were attributed to different forms of violence and 353 were the subject of coroners' inquests. The causes of 28, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Sheffield, Leeds, Bristol, Bradford, Hull, and in 55 other smaller towns. Of the 28 uncertified causes of death, 7 were recorded in Birmingham, 2 in Grimsby, and 2 in Rhondda.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1034 births and 608 deaths were registered during the week ended Saturday, Nov. 8th. The annual rate of mortality in these towns, which had been 13·9, 14·0, and 14·7 per 1000 in the three preceding weeks, declined to 14·0 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 14·3, against 13·6 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rate last week ranged from 5·4 in Hamilton, 6·0 in Kilmarnock, and 6·1 in Clydebank, to 15·3 in Edinburgh, 15·6 in Coatbridge, and 17·9 in Dundee.

The 608 deaths from all causes were 27 fewer than the number in the previous week, and included 55 which were referred to the principal epidemic diseases, against 62 and 82 in the two preceding weeks. Of these 55 deaths, 19 resulted from infantile diarrhœal diseases, 11 from measles, 11 from diphtheria, 10 from scarlet fever, and 4 from whooping-cough, but not one from enteric fever or from small-pox. These 55 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·3 per 1000, which coincided with the rate in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 29, 19, and 34 in the three preceding weeks, declined to 19 last week; of this number 11 were registered in Glasgow and 4 in Edinburgh. The deaths referred to measles, which had been 14, 12, and 17 in the three preceding weeks, fell to 11 last week, of which 5 were recorded in Glasgow and 2 in Edinburgh. The fatal cases of diphtheria, which had been 8, 11, and 11 in the three preceding weeks, were again 11 last week, and comprised 5 in Glasgow, 3 in Aberdeen, 2 in Greenock, and 1 in Dundee. The deaths attributed to scarlet fever, which had been 13, 11, and 14 in the three preceding weeks, declined to 10 last week, of which 4 occurred in Glasgow. The 4 deaths referred to whooping-cough were slightly below the average in the earlier weeks of the quarter.

The deaths referred to diseases of the respiratory system, which had been 80, 92, and 99 in the three preceding weeks, declined to 84 in the week under notice; 29 deaths were attributed to different forms of violence, against 18 and 32 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 595 births and 404 deaths were registered during the week ended Saturday, Nov. 8th. The annual rate of mortality in these towns, which had been 16·0, 17·8, and 17·2 per 1000 in the three preceding weeks, rose to 17·6 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 17·3 per 1000; in the 96 large English towns the corresponding rate did not exceed 13·6, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 19·4 in Dublin (against 13·0 in London and 14·6 in Glasgow), 17·5 in Belfast, 18·4 in Cork, 21·6 in Londonderry, 21·7 in Limerick, and 20·9 in Waterford, while in the 21 remaining smaller towns the mean death-rate did not exceed 12·0 per 1000.

The 404 deaths from all causes were 9 in excess of the number in the previous week, and included 34 which were referred to the principal epidemic diseases, against numbers steadily declining from 132 to 41 in the eight preceding weeks. Of these 34 deaths, 16 resulted from infantile diarrhœal diseases, 8 from scarlet fever, 5 from whooping-cough, 3 from measles, 1 from enteric fever, and 1 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·5 per 1000, against 1·3 in the 96 large English towns and in the 16 Scotch towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily decreased from 111 to 27 in the eight preceding weeks, further declined to 16 last week, and included 7 in Dublin, 3 in Belfast, and 2 in Kilkenny. The deaths referred to scarlet fever, which had been 4, 9, and 5 in the three preceding weeks, rose to 8 last week, and comprised 7 in Belfast and 1 in Dublin. Of the 5 fatal cases of whooping-cough, which were slightly in excess of the average in the earlier weeks of the quarter, 3 occurred in Galway. The 3 deaths attributed to measles were equal to the average in the three preceding weeks, and comprised 2 in Dublin and 1 in Londonderry. The death from enteric fever occurred in Belfast, and that from diphtheria in Dublin.

The deaths referred to diseases of the respiratory organs, which had been 48, 53, and 61 in the three preceding weeks, further rose to 69 in the week under notice. Of the 404 deaths from all causes, 127, or 31 per cent., occurred in public institutions, and 9 resulted from various forms of violence. The causes of 13, or 3·2 per cent., of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death did not exceed 0·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: E. G. E. O'Leary to the *Invincible;* and H. Spicer to the *Indefatigable.* Surgeons: S. Punch to the *Indefatigable;* and E. Moxon-Browne to the *Tamar*, additional, for Hong-Kong Hospital, and to the *Triumph*, additional, for Hong-Kong Hospital, on the *Triumph* replacing the *Tamar.*

The undermentioned Acting Surgeons have been confirmed in the rank of Surgeon in His Majesty's Fleet:—Percy Lemprière Gibson (dated Oct. 4th, 1912), Arthur Martin Henry, George Foster Braithwaite Page, Alexander John Patterson, William Agar Scholefield Duck, Frederick Cecil Wright, Bernard Edward Patrick Sayers, David Greig Arthur, Alexander Simpson, Henry Ellis Yeo White, Michael Meehan, Devonshire Penrose Hawkes Pearson, Ivor Stanley Gabe, and Arthur John Tozer (dated April 11th, 1913).

ROYAL ARMY MEDICAL CORPS.

Major Edmund P. Hewitt is placed temporarily on the half-pay list on account of ill-health (dated Nov. 7th, 1913).

Colonel J. Maher has relinquished charge of the Queen Alexandra Military Hospital and taken up duty in the Gibraltar Command as Assistant Director of Medical Services.

Lieutenant-Colonel J. J. Gerrard, senior medical officer in the Sierra Leone Protectorate, has arrived home for duty from West Africa. Lieutenant-Colonel H. N. Thompson, D.S.O., has been appointed to the Scottish Command. Lieutenant-Colonel C. C. Reilly has been appointed to hold charge of the Military Hospital at Colaba, Bombay. Lieutenant-Colonel J. W. Bullen has been appointed to the Northern Command for duty. Lieutenant-Colonel H. D. Rowan has been appointed to hold charge of the King George V. Military

Hospital at Arbor Hill, Dublin. Lieutenant-Colonel M. O'D. Braddell has been appointed to the Irish Command for a tour of duty. Lieutenant-Colonel G. S. McLoughlin, D.S.O., has been appointed to hold charge of the Military Hospital at Winchester.

Major A. D. Waring has taken up duty at the Milltary Hospital, Hilsea. Major W. Tibbits has embarked for a tour of service in India. Major A. W. A. Irwin has joined at Cork. Major J. C. B. Statham has arrived home for duty from the Sierra Leone Protectorate. Major D. J. Collins has been transferred from the Military Hospital at Poona Cantonment to Kirkee. Major G. B. Crisp has arrived in Hong-Kong for a tour of service. Major H. W. Long has taken up duty at the Military Hospital, Devonport. Major B. B. Burke has been appointed to the Military Hospital at Dover. Major H. L. W. Norrington has arrived home on leave of absence from the Military Hospital at Malta. Major E. A. Bourke has been appointed for duty at the Military Hospital, Pembroke Dock. Major N. J. C. Rutherford has been selected for appointment as Specialist Sanitary Officer to the Cork District. Major C. W. Reilly has been appointed to hold medical charge at Bodmin.

Captain J. T. McEntire has arrived home on leave of absence from the Sierra Leone Protectorate. Captain N. E. J. Harding has been appointed to the London District for a tour of duty. Captain L. A. A. Andrews has been transferred to the Northern Command from the Military Hospital at Cork. Captain W. G. Maydon has been selected for appointment as Adjutant to the Royal Army Medical Corps School of Instruction in the West Lancashire Division. An exchange on the roster for service abroad has been approved between Captain C. P. O'Brien-Butler and Captain H. L. Howell. Captain W. F. H. Vaughan has embarked for a tour of service in Malta. Captain C. M. Drew has arrived home on leave of absence from Cairo. Captain B. A. Odlum has been selected for appointment as Instructor in Medical Corps duties at the South African Medical College. Captain J. G. Bell has embarked for a tour of service in the Straits Settlements. Captain H. J. Crossley has been appointed to the Military Hospital at Meerut Cantonment. Captain W. R. O'Farrell has arrived home on leave of absence from the Military Hospital at Alexandria. Captain P. J. Hanafin has been transferred to the Military Hospital at Dublin from Rogerstown Camp. Captain H. M. J. Perry has been selected for appointment as Specialist in Bacteriology and Prevention of Disease at Devonport. Captain A. W. Bevis has joined at Belfast. Captain W. E. Marshall has arrived home on general leave of absence from the Military Hospital at Cairo. Captain T. S. Dudding has been placed under orders for a tour of duty in India. Captain H. W. Russell has embarked for a tour of service in India. Captain A. C. Osburn has taken up duty at the Royal Victoria Hospital, Netley. Captain C. T. Edmunds has been transferred from Fawley Court to Bulford Camp. Captain W. Mathieson has arrived home on general leave of absence from the Military Hospital at Pretoria. Captain F. C. Sampson has been selected for appointment as Specialist in Dermatology and Venereal Diseases. Captain M. J. Lochrin, Captain E. M. Middleton, and Captain A. W. Howlett have been placed on duty on board the transport ss. *Plassy*, which left Bombay for Southampton on Nov. 7th with time-expired troops. Captain A. S. Arthur has been appointed to the Military Hospital at Liverpool. Captain T. W. Stallybrass has arrived home on general leave of absence from the Military Hospital at Khartoum. Captain R. C. Hallowes has been appointed to the Military Hospital at Omagh. Captain W. J. E. Bell has joined the London District for a tour of duty. Captain E. C. Lang has been transferred from Maryborough Heath Camp to the Military Hospital at the Curragh. Captain T. C. C. Leslie has taken up duty at the Military Hospital, Cork. Captain R. E. Porter has been transferred from Poeghane Camp to the Military Hospital at Nenagh. Captain F. A. H. Clark has been appointed to hold charge of the Brigade Laboratory at Calcutta. Captain A. D. Fraser has been appointed to the Royal Victoria Hospital at Netley, on transfer from London. Captain P. M. J. Power has been appointed to the Military Hospital at Cosham. Captain A. M. Pollard has been appointed for duty to the Military Hospital at Colchester. Captain C. A. T. Cunningham has been appointed Specialist in Dermatology and Venereal Diseases to the Fifth (Mhow) Division of the Southern Army in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel G. G. Giffard has taken up duty as Superintendent of the Government Maternity Hospital, Madras Presidency. Lieutenant-Colonel A. E. Berry has been granted general leave of absence home from India for one year. Lieutenant-Colonel H. E. Banatvala has been appointed to officiate as Inspector-General of Civil Hospitals and Prisons and Sanitary Commissioner in Assam, vice Colonel R. N. Campbell, C.B., C.I.E., who has arrived home on leave.

Major H. B. Foster has been appointed to officiate as Professor of Medical Jurisprudence at the Goverment Medical College, Calcutta, during the absence on leave of Major O. St. John Moses. Major A. E. J. Lister has been appointed Professor of Physiology on the staff of King George's Medical College at Lucknow. Major A. M. Jukes has been confirmed in his appointment as Deputy Sanitary Commissioner to the Burdwan and Presidency circles in Bengal. Major J. W. Grant has been granted privilege leave of absence by the Government of India. Major H. A. J. Gidney, civil surgeon at Naga, has been deputed to Delhi by the Assam Administration in connexion with the prevention of malarial fevers.

Captain A. J. V. Betts has been granted leave of absence on medical certificate. Captain F. P. Mackie has been appointed to the Bacteriological Department of the Government of India. Captain H. C. Keates has been granted leave of absence. The services of Captain M. J. Quirke have been placed permanently at the disposal of the Government of Madras for employment in the Sanitary Department. Captain R. E. Flowerdew has been appointed to hold substantive medical charge of the 99th Regiment of Deccan Infantry. Captain J. S. Fitzgerald has been selected for appointment in the Bombay Jail Service. The services of Captain W. S. McGillivray have been placed temporarily at the disposal of the Burmese Administration for employment on plague prevention duty. Captain N. M. Wilson has been granted leave of absence. The services of Captain S. J. Bathena have been replaced at the disposal of the Commander-in-Chief. Captain A. C. Ingram has taken up duty in Madras Presidency.

Lieutenant P. F. Gow has been selected for appointment as Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Brigade Headquarters, Allahabad. Lieutenant P. J. Veale has been granted eight months' general leave of absence home from India on medical certificate.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Thomas Lindsay to be Captain (dated Nov. 12th, 1913). Lieutenant George Rollason resigns his commission (dated Nov. 12th, 1913). Lieutenant Frederick L. Tulloch is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Colonel William Coates, C.B., Territorial Force Reserve, is appointed to the Honorary Colonelcy of the Royal Army Medical Corps in the East Lancashire Territorial Division (dated Nov. 12th, 1913).

Colonel Joseph Whitfield Blandford, Retired List (late of the Army Medical Service), is appointed to the Honorary Colonelcy of the Royal Army Medical Corps in the Northumbrian Territorial Division, vice Honorary Colonel Sir George H. Philipson, Knight, who vacates the appointment (dated Nov. 11th, 1913).

6th London Field Ambulance, Royal Army Medical Corps: Lieutenant Frank Colman, from the 5th London Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Oct. 13th, 1913).

3rd Lowland Field Ambulance, Royal Army Medical Corps: Captain James H. H. Pirie is seconded under the conditions of paragraph 112 of the Territorial Force Regulations, for service under the Colonial Office (dated Oct. 1st, 1913).

2nd London (City of London) General Hospital, Royal Army Medical Corps: Captain Henry P. Dean resigns his commission (dated Nov. 12th, 1913).

1st Western General Hospital, Royal Army Medical Corps: Lieutenant-Colonel Thomas H. Glynn resigns his commission (dated Nov. 12th, 1913). Major Sir Ronald Ross, K.C.B., to be Lieutenant-Colonel (dated Nov. 12th, 1913). Captain Peter Davidson to be Major (dated Nov. 12th, 1913). Captain

Arthur John Evans, from the 1st West Lancashire Field Ambulance, Royal Army Medical Corps, to be Captain, whose services will be available on mobilisation (dated Nov. 12th, 1913).

Attached to Units other than Medical Units.—Lieutenant James M. Kirkness to be Captain (dated August 1st, 1913). The undermentioned Lieutenants resign their commissions (dated Nov. 12th, 1913): Richard C. Roberts and Frederick G. Harper.

THE ROYAL AUTOMOBILE CLUB AS A HOSPITAL IN TIME OF WAR.

At a recent meeting of the committee of the Royal Automobile Club the following resolutions were adopted :—

1. That in the opinion of this committee it is desirable that in the event of war calling for the mobilisation of the Territorial Forces in this country, the Royal Automobile Club be handed over to the London County Territorial Association and other analogous bodies, to be a general hospital, and this committee pledges itself to do everything in its power to secure the carrying into effect of this resolution.
2. That the R.A.C. be No. 3 General Hospital, as that hospital is commanded by Dr. H. E. B. Bruce-Porter, a member of the committee of the club, who would therefore be in touch with the R.A.C. staff.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the November issue of the *Journal of the Royal Army Medical Corps* Colonel W. H. Horrocks returns to the subject of the variation of the bacillus typhosus. His present conclusions are that under certain conditions B. typhosus may be converted into B. fæcalis alkaligenes, but he is unable to afford any evidence as to the epidemiological significance of this variation. "The B. fæcalis alkaligenes appears to have no pathogenic effect on ordinary laboratory animals, and it has not been possible to reconvert this variant into the B. typhosus." The military great coat, which, by the way, we do not hear of being used in the British army until the reign of Elizabeth, is the subject of a very interesting article by Captain N. Dunbar Walker, who discusses the construction and use of this garment by the armies of Europe, of America, and of Japan. Dairies and Cowsheds, their Effect upon the Purity of the Milk Supplied to Military Hospitals, Troops, and Married Families, by Staff Sergeant E. B. Dewberry, R.A.M.C.; Kala-Azar in an Adult from Malta, by Fleet-Surgeon P. W. Bassett-Smith; a case of Death from Syphilis occurring Nine Days after Injection of Salvarsan, by Captain J. H. Duguid and Lieutenant W. T. Graham; and the Phylactic Use of Quinine, by Lieutenant-Colonel H. N. Thompson, are other matters dealt with in the present issue of the *Journal*. Students of military history will appreciate the excerpts from old records by Colonel R. H. Firth on Some Indian General Orders.

NAVAL MEDICAL CONSULTATIVE BOARD.

Surgeon-General John J. Dennis has been appointed a naval member of the Naval Medical Consultative Board in the place of Surgeon-General Howard Todd, C.B., K.H.S., retired. Sir John Tweedy has been appointed a civilian member of the Board.

MIDDLESEX COUNTY COUNCIL AND THE TREATMENT OF TUBERCULOSIS.—It was reported at the last meeting of the Middlesex county council that a number of applications had been received from non-insured persons suffering from tuberculosis for institutional treatment. Hitherto sanatorium treatment had been limited to insured persons, but the public health committee stated that sufficient progress had now been made for it to be possible to begin the treatment of non-insured persons. Seeing that insured persons contributed towards the cost of sanatorium benefit it would only be equitable that a contribution towards the cost should be made by non-insured patients, the amount being considered in each case on the merits. The council passed the following resolutions :—

That where the council think it advisable the treatment of non-insured persons suffering from tuberculosis be undertaken at hospitals, sanatoriums, and dispensaries by the county council upon the basis of a contribution being made, where possible, by the patient towards the cost of maintenance or treatment.

That institutional treatment be undertaken only so far as accommodation is available at any of the hospitals or sanatoriums under the control of the county council, or to which it has agreed to send patients.

That the public health committee be authorised to sanction the above treatment and to settle the amount of the contribution, if any, in each individual case.

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

A Stand-to-Stand Visit of Inspection at the Olympia Exhibition.

WITH over 300 exhibits, the doctor in search of a car will feel confused unless he relies rigidly upon one factor in his choice—namely, the price which he will give. Generally speaking, there are two classes of doctors who need motors. There is the town and country specialist, to whom price is of little importance, and who will find in either a Rolls-Royce, a Delaunay-Belleville, an Armstrong-Whitworth, a Wolseley, a Lanchester, a Renault, a Sunbeam, a Vauxhall, a Fiat, a Minerva, a Napier, or a Clement-Talbot a car that will fulfil all his wants. Any of these are sure to give satisfaction, the price varying from about £1200 or £1300 for a Rolls-Royce to about half, or less than half, of that amount for some of the cheaper makes. The other class is the general and country practitioner, and the question of expense with the major part of them has to be considered. This class can probably be again divided into two — those who merely want a two-seater for their professional work, and those who would like a car which they could also use for week-end or other holidays with their families. If it is a matter of expense, it should be borne in mind that the light two-seater is much cheaper, not only to buy, but also in running cost and upkeep.

Messrs. Alldays and Onions show their two- and four-cylinder models. Their new four-cylinder 10 h.p. is a model of sound engineering, and one worthy of the doctor's consideration. The brake adjustment is by means of thumbscrews in very accessible positions, and the body provides plenty of room for the occupants. The 10 h.p. Midget has a two-cylinder engine, and makes an excellent light two-seater.

Messrs. Argylls, Limited, show on Stand No. 73 their 12–18 h.p. poppet valve and samples of their later models of sleeve Argyll engines. Their coachwork as well as their chassis is bound to attract great attention.

The Ariel and General Repairs, Limited, show the Hurtu 10 and 14 h.p. cars, both with four cylinders. Little alteration has been made to their last year's model, except that now the gearbox gives four forward speeds, and provision has been made at the foot of the engine for fixing a dynamo for lighting purposes.

Messrs. Bayard show a two-seater torpedo fitted with a four-cylinder 60 mm. × 120 mm. engine. The polished mahogany covering for the petrol tank and one-man type hood make the model very attractive.

Messrs. F S. Bennett, Limited, show on Stand No. 108 the new Cadillac motor. This is certainly replete with novelties; these include two direct drives by means of two pairs of bevel gears, either for working alternatively or giving the car two different gear ratios. An electric starter is also fitted, and the gears are changed by means of an electric control.

Briton Motors Company, Limited, show their two-seater, fully equipped with a 68 mm. × 120 mm. four-cylinder engine, which has been previously described in these Notes, and should certainly be inspected by the doctor in search of a car at less than £200. The price is 175 guineas for a two-seater and £200 with a four-seated streamline body.

The exhibit of the Darracq Company has always been of interest. This year the great attraction is their 12 h.p. and 16 h.p. car, designed by Mr. Owen Clegg. Both are full of new features. The chassis cannot claim all the improvements, for the coachwork fitted shows a very marked advance both in design and workmanship, and it is pleasing to note that this also is produced in the Darracq factory at Fulham. The 12 h.p. is shown as a torpedo and limousine landaulette. There will be a large sale of this high-class model.

The models of the De Dion Bouton Company are to be seen on Stand No. 74, the most noticeable feature being the

introduction of a small four-cylinder model in place of the twin-cylindered model used for so many years past. This new 8–10 h.p. chassis has a four-cylindered 56–120 mm. monobloc engine, and is supplied as either a two-, three-, or four-seated car. It has a chain-driven single camshaft, chain drive to magneto and oil pump, and thermo-syphon cooling, assisted by a fan mounted on an adjustable bracket. The valves are enclosed, the carburetter is the De Dion-Zenith, and the magneto is a Bosch. The price for chassis, tyres, and tool kit is £221. Other models are also shown.

The Hillman Motor Company show four types of their new 9 h.p. car, fitted either as a two-seater with hood, &c., or as a two-seater coupé, which would make a very useful car for professional use.

Messrs. Metallurgique, Limited, are on Stand 99. Their 15–20 h.p. is an improved edition of their 1913 type. A special platform is arranged for an electric light dynamo, and, as is now so universal, the valve gear is driven by a silent chain.

Messrs. Morgan and Co. exhibit on Stand No. 80 three entirely new Adler models. There is a 9 h.p. with a four-cylinder monobloc engine 65 × 98 mm., complete with Morgan two-seated body, also a chassis of the same type. They also manufacture a tandem two-seater on this chassis, and it is essentially one that should be considered by all in search of a light two-seater. The 11–16 h.p. chassis has a four-cylinder engine 67 × 110 mm., cast in pairs, fitted with the latest design Morgan coupé-landaulette body, and the 20–30 h.p. chassis has a four-cylinder engine 86 × 135 mm., equipped with the "Morgan" new patent cabrio-landaulette body. The popular 14–18 h.p. model, fitted with the latest design "Morgan" torpedo body, is also shown.

Messrs. W. R. Motors, Limited, show the Morris-Oxford Light Car, which has a White and Poppe engine and carburetter, and all the brakes are on the back axle. Three-quarter elliptic springs are fitted, so the riding should be most comfortable. The price for a two-seater model de luxe is 190 guineas, complete with Sankey detachable wheels, but the ordinary type is listed at £180. This little two-seater is especially worth close inspection.

The cars of the Rover Company, Limited, have always appealed to doctors, and their exhibit of their 12 h.p. models, with different type bodies, should certainly attract attention. There is little alteration in their 1914 cars, except that the wheel-base has been increased and a dynamo lighting outfit is supplied as a standard equipment.

The Sunbeam Company show on Stand 101 some very good examples of their 12–16 and 16–20 chassis. There are no changes to record in the main design of this car, last year's models having given such universal satisfaction.

The Swift Company, on Stand 42, show samples of their 11·9 and 15·9 cars. The former as a two-seater is sold at £285, and the latter with a streamline body, including a dynamo electric lighting set, is £385. Both of these cars are certainly worthy of close attention by those who can run to these prices.

Clement Talbot, Limited, show four cars. Their 12 h.p., which sells at £410 complete, is the one most likely to appeal to doctors.

The Vulcan Motor and Engineering Co., Limited, have made practically no changes in their 10 h.p. engine, but their 15 h.p. model has a new monobloc engine. A good many doctors have had these cars and have reported most favourably concerning them.

The stands of the Belsize Company and of the Star Engineering Company should be visited, as both make cars eminently suitable for medical men.

Tyre exhibits are always interesting, and the points which seem to have advanced are the greater use of bolt-plate valves and detachable rims and wheels.

The Warland detachable rim, which is used on a good many cars, including the De Dion, certainly seems a favourite, and is to be recommended. All the tyre manufacturers are well represented in the gallery—the Dunlop, the Continental, the Michelin, the Palmer, the Stepney Spare Motor Wheel, Limited, and the Wood-Milne, Limited. The two latter have exceedingly satisfactory all-rubber non-skids, and the manufacturers named produce goods that can certainly be relied upon.

From tyres it is but a step to tyre-repairing appliances, and those of Messrs. Harvey Frost and Co., Limited, create genuine interest on account of the new models and the important additions to existing models.

Messrs. H. M. Hobson, Limited, show a full range of sparking plugs. This year they have brought forward a new type of plug, which is shown at Olympia for the first time, and will be on sale on and after December 1st. The special purpose of this plug is to do away with the wear of the electrodes due to the action of the voltaic arc when the engine is running. This voltaic arc volatilises the molecules of the electrodes, and in consequence the distance between the sparking points widens, and renders easy starting, or starting at all, impossible. Similarly, the electrode may melt and the spark lose its energy, or surplus oil sticking on the electrodes may cause other troubles. The new arrangement of the patent expanding electrode does away with these troubles. The insulated centre stalk is made in its whole length of two metals, riveted and soldered together, but with different co-efficients of expansion. Owing to its varying expansion this centre stalk bends more and more as the heat increases, hence it can be easily understood that this electrode, when brought nearer to the electrode attached to the body of the plug, facilitates the starting of the engine, as the spark jumps across easily. Then, as the speed of the engine increases, the patent electrode gets hotter and hotter, and consequently bends farther away from the electrode on the body of the plug, and this wider gap causes the spark to give out its maximum heat and power at all speeds of the engine.

Messrs. Brown Bros., Limited, have an interesting range of motor accessories, such as the Brolt electric lighting installation, the autoclipse lamps made for either acetylene or electricity, the popular Gabriel horn, the shock absorber which was described previously in these Notes, as well as the Sampson plug for repairing punctures, which was also recently fully described. A great many owners like to do a good bit of repairing work themselves, and for those who care to remove the carbon deposit from their cylinders, instead of having it burnt out, the "Success" carbon-removing tools will appeal. They enable the cylinder head and piston to be thoroughly scraped as well as the edges of the parts. After the carbon has been scraped the deposit can be blown into the valve chambers by a tyre pump, whence it can be spooned up by means of the special tools provided.

Speedometers are accessories which, though not necessary, are certainly very much in favour. Messrs. Stewart have always produced a reasonable and popular one, and their 1914 models have certainly an advantage over the older ones, as provision is made for lubrication of the wheel-driven bevels, which in the older days occasionally gave trouble through wear. Messrs. S. Smith and Son and Messrs. Markt and Co. also show excellent speedometers, which are sure to give satisfaction.

Some who have to travel in all weathers may be attracted by the Thompson-Bennett exhaust car heater. This firm also show the warning-tone horn, which is merely worked by a small hand plunger, without the use either of a mechanical driver or of electricity.

Electric car lighting has now become almost a necessity, especially for doctors. Of course, accumulators can be used and will supply sufficient current for ordinary side and head lights, but they have to be kept charged, and occasionally they may get run down and cause anxiety as to whether the light will last for the return home journey. This, of course, should not occur if they are kept charged, but all this worry can be avoided by an electric light installation driven off the engine.

The Imperial Motor Industries, the Motor Accessories Company, Messrs. S. Smith and Sons, the Rotax Motors Accessories Company, Messrs. Peto and Radford, the Mira Magnetolite, and Messrs. C. A. Vandervell and Co. all show exceedingly neat dynamos and fittings for car lighting. That shown on the stand of the Imperial Motor Industries is of exceptional interest, as it also combines a self-starter. The question whether a high voltage or low voltage is preferable is greatly a matter of taste. The writer rather inclines to a low voltage, and one point which he thinks should be insisted upon is that the dynamo can easily be disconnected when not required for accumulator charging or lighting.

The Atlas Inner Case Syndicate show a useful petrol filler, which is also a strainer, as well as their impulse pump,

which latter is certainly of value, and was fully described some time ago in these Notes.

The Scott's Starter Syndicate, Limited, also show an efficient electric starter and lighting generator.

The general impression of the exhibition is that it is very much like its predecessors, except that there are more exhibits. Leather-faced cone clutches are as popular as ever, for which I think the doctor should be grateful, as they are satisfactory, and even if the leather does wear it can easily be replaced. Four-speed gear boxes are ousting the three-speed, and smaller engines are more universal. The exhibition is certainly like a good pudding—it has plenty of plums in it, and there is now much more likelihood of a purchaser drawing a plum than there was in the past.

Any of the cars mentioned above can, in the writer's opinion, be safely bought by doctors with almost a certainty of good and efficient service, provided the purchaser, either personally or by his chauffeur, takes care of his car.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Cremation in Manchester.

FROM the annual report of the Manchester crematorium we learn that the cremations last year reached 159, the numbers for the four previous years being 117, 110, 113, and 147. The number of visitors paying for admission to see the crematorium (1667) also showed an increase. The numbers present at cremation funerals reached 5330. The directors state that attendance at cremation funerals is largely effective in removing prejudice against cremation. There are 13 crematoria in the kingdom, and only one, that at Golder's Green, had more cremations last year than the Manchester crematorium. After defraying all expenses there is a surplus of £418, while the accumulated surplus amounts to £634, and the reserve account stands at £800.

Burnley Victoria Hospital.

Mr. Edward Green has intimated to the Burnley Victoria Hospital authorities that his wife and her sister, Mrs. Greenhalgh, will contribute £1000 for a cot to be placed in their names in the female ward.

The Birth-rate in Manchester.

Dr. E. Sergeant, the county medical officer, in his recent report stated that the birth-rate for Lancashire in 1912 was the lowest on record, with the exception of 1910. In Manchester up to the end of September there has been an appreciable increase in the birth-rate.

Nov. 11th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Dinner of the Medical Institution.

THE biennial dinner was held on Nov. 8th at the Exchange Station Hotel, when about 160 members and guests sat down. Among the guests were the Bishop of Liverpool, the Lord Mayor, Dr. W. S. A. Griffith, and the Presidents of the medical societies of Chester, Birkenhead, St. Helen's, and Wallasey. Mr. Robert Jones, the President of the society, was in the chair. After the usual loyal toasts, Dr. Caton proposed "The City and Port of Liverpool," and spoke of the many improvements that were taking place. The Lord Mayor, in replying, paid a high tribute to the work of the profession, and more especially to the work of the Tropical School, inasmuch as the world owed the completion of the Panama Canal to tropical research. He thought the greatest requirement now was better means of communication between the two banks of the river, so as to unite the population of the district. The Bishop of Liverpool proposed "The Liverpool Medical Institution," and gave a short account of its origin in the eighteenth century and how it had grown by the union of three parent societies between 1830 and 1840. He said it was owing to the Medical Institution that the idea of a Liverpool University had begun. The President, in replying, said that the institution could boast of as great activity and as large meetings as any society in the country. Dr. Griffith, in replying for the guests, said that Dr. Rutter, in founding the society in its present form, had hoped that it might and would be the means of uniting its members in a firm and compact body, working on individualistic lines but in friendliness and with mutual esteem. A society such as this, by bringing its members constantly into contact with one another, might fulfil the wishes of its founder.

Visit of Sir Dyce Duckworth.

Sir Dyce Duckworth has been visiting the city of his birth as the guest of Mr. T. H. Bickerton, who entertained a large party at dinner to meet him before the meeting at the Medical Institution. After the meeting there was an informal gathering at Mr. Bickerton's house, when about a hundred medical men had the pleasure of hearing from Sir Dyce Duckworth his reminiscences of bygone Liverpool medical men. Among a large number of past leaders Sir Dyce Duckworth paid especial tribute to the Bickersteths, quoting Symes as having said that E. R. Bickersteth was "the finest surgeon in England."

The Passing of Two Notabilities.

Two well-known figures for many years connected with the Royal Infirmary have passed away—the Rev. William Smith and Mr. James Lister. Mr. Smith was chaplain at the infirmary from 1865 until he resigned about a year ago. He died quite suddenly on his way to church on Sunday, Oct. 26th. Mr. Smith had qualified as a medical man. Under rather an austere exterior there was a kindly personality which endeared him to those who really knew him. Mr. James Lister had for many years been a member of the committee of the Royal Infirmary, in which he took the greatest possible interest, making frequent visits there and personally knowing many residents, nurses, and patients.

Nov. 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculosis in Lanarkshire.

ARRANGEMENTS are now in progress for a joint sanatorium for the burghs of Hamilton, Motherwell, Wishaw, and Rutherglen, and a site has been purchased on the estate of Muirbank, Strathaven. It is proposed to build a hospital pavilion for 20 beds, two chalet pavilions, each with 20 beds, and two shelter pavilions of the same capacity; an administrative block (for which Muirburn House will be

utilised), including nurses' accommodation; medical superintendent's house, porter's lodge, and six houses for workmen, along with accessory buildings and plant. The estimated cost is £30,000.

Medical Arrangements for Lothian Miners.

An agreement has been come to between the doctors of Mid and East Lothian and the Miners' Federation, whereby medical attendance will be given to the families and dependents of miners. The men are to be allowed to select their own doctor, and will pay a flat rate of 1½*d.* a week, or 2*d.* per week including medicine. Cards will be issued to all the miners on Nov. 15th, and the doctors will have duplicate cards in order that they may know how many individuals the various colliery companies are thus responsible for.

Nov. 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Insurance Commissioners and the Medical Profession.

SEVERAL Insurance Committees have already passed resolutions urging the Insurance Commissioners to use their best exertions to come to an amicable agreement with the medical profession. Some of the more important Approved Societies have expressed the opinion that without the goodwill of the profession it was impossible to work the Act with success. Whatever may have been the operating cause, the Irish Insurance Commissioners, after some six months' cessation of intercourse, have resumed communication with the authorised representatives of the profession, as I announced last week. As the Irish Medical Committee is already accredited to speak for the profession, it possesses all the requisites demanded by the Commissioners for making definite terms, and rumour has it that the Commissioners will be prepared to offer terms which the profession may find itself able to accept.

Evening Dispensaries for Poor-law Medical Officers.

The Cork guardians in appointing a medical officer recently stipulated that, in addition to attending a daily dispensary in the morning, he should also attend for half an hour each evening. As far as I know, no evening dispensary has hitherto been held under the Poor-law in Ireland. Commenting on the proposal of the Cork guardians, the Local Government Board remarked that the medical officer would not be able in the evening to give the individual care and attention to the patients which their condition would require, as he would then be tired after his day's work. Punctual attendance in the evening might also occasionally curtail within narrow limits the time for visiting patients in their own homes. The Board, it was added, would sanction, as a tentative measure, the opening of the dispensary on two evenings a week, on condition that attendance thereat should be limited to persons who, owing to their employment, were prevented from attending the morning dispensary.

The Scarlet Fever Epidemic in Belfast.

At the monthly meeting of the City Corporation of Belfast held on Nov. 3rd it was reported that 378 cases of infectious disease had been notified in Belfast between Sept. 14th and Oct. 18th, and of these 264 were of scarlet fever. During the previous five weeks the number of notifications of infectious disease was 286, and the number was 235 in the corresponding period of last year. The chairman of the public health committee said, in submitting the health report, that the increase was due entirely to the large number of cases of scarlet fever. "They were just suffering as all large cities suffered," and that "it (scarlet fever) was a disease that it was practically impossible to control the spread of when it had developed to a certain extent, but everything that could be done to control the spread of it was being done." The situation is becoming too serious for a do-nothing policy. At a meeting of the public health committee held on Nov. 6th it was reported that there had been notified during the week ended Nov. 1st 66 cases of scarlet fever, which is six less than in the previous week. The epidemic is still raging, and at the present time there are in the two fever hospitals about 430 cases, and—what is worse—the type of the disease is severe, bad septic throats and nephritis being common.

Royal Victoria Hospital, Belfast.

At a meeting of superintendents of the various districts in connexion with the Royal Victoria Hospital special Saturday collection it was reported that a sum of £1011 had been handed over to the hospital authorities as the result of this special effort. This was £44 more than last year. The expenses were £79.

Down County Council and Tuberculosis.

The Down county council decided on Nov. 6th to adopt a scheme for the treatment of tuberculosis, which contemplated a sanatorium with 75 beds, together with a central dispensary and five branch dispensaries, the charge to the rates being reckoned at about £2569.

The Late Mr. William Watts Thetford.

I regret to announce the death, at the age of 90, at his residence, Strangford, Co. Down, of Mr. W. W. Thetford, M.R.C.S. Eng., L.R.C.P. Irel., who was the oldest medical practitioner in Ireland. Born at Clones, Co. Monaghan, on March 19th, 1823, Mr. Thetford was the son of Mr. Joseph Thetford, who was of English descent, having come from a Norfolk family, while his mother, a daughter of Major H. W. Stephens, of Co. Fermanagh, was of the blood of the Argyles, and with his family remains the old marble bowl of Inverara, with inscription, attesting his descent from the Argyles. Dr. Nicholas Thetford, grandfather of the deceased, and his seven uncles were doctors. In 1849, after studying at Trinity College, Dublin, and at the Richmond Hospital, Mr. Thetford obtained the M.R.C.S. Eng., and in the following year that of L.R.C.P. Irel. For half a century he resided at Strangford, Co. Down, where he had one of the very best practices in Ireland, his *clientèle* including a very large number of the principal families for many miles round his home.

Nov. 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Professor Charles Richet and the Nobel Prize.

THE Nobel prize for medical science has been awarded this year to Professor Charles Richet, who received the news by telegram while attending the marriage of his son. The award has been acclaimed in France as having fallen to a French *savant* who is held in the highest regard. Already the award of the Moscow prize at the congress in London for

his researches on anaphylaxis had drawn to him the attention of the scientific world, and had, perhaps, prepared it for the award of the Nobel prize. M. Charles Richet, who was born in 1850, the son of a famous surgeon himself a professor at the Paris Faculty of Medicine, was nominated *agrégé* of the Faculty of Paris in 1878, and in 1887 succeeded Béclard in the chair of physiology in the same Faculty. Among his numerous works the best known are the discovery of serotherapy and of anaphylaxis. He it was who, in 1888, in collaboration with Héricourt, first showed that by the injection of the serum of vaccinated animals into other animals the same immunity was transferred to them. The first injection in serumtherapy in man was made by Richet in December, 1890, and it was only shortly afterwards that Behring and Roux applied this discovery to diphtheria by the method that is now general. The discovery of anaphylaxis was a consequence of researches on the toxicity of the poison of actinia in 1902. Richet, while trying to determine the toxic dose, was struck with the fact that animals inoculated with a sufficiently powerful dose, yet failing to succumb, died when inoculated later with a much weaker dose. He divined the significance of this fact, which has entirely upset our ideas based on the mechanism of an immunity created by weak and progressive doses. Charles Richet is, moreover, one whose inquiring mind wanders over every field. He has occupied himself with aviation, psychical science, telepathy, pacificism, literature, poetry, and the drama. He is president of the Société Français pour l'Arbitration des Nations.

X Ray Burns.

A procedure has been put forward which appear to afford a definitive protection against the X rays in the case of operators who have to manipulate the apparatus during long periods. Hitherto, specially made gloves which absorb from 60 to 80 per cent. of the X rays have been used, but these gloves still remained permeable to the hard rays. Dr. Ménard, head of the radiographic department at the Hôpital Cochin, has devised a method which appears to afford perfect protection, and this has been brought before the Academy of Sciences by M. Moureu. A special cupboard or chair is used, the three panels of which are furnished inside with sheets of lead at least 4 millimetres thick. Both the patient and the ampoule are placed inside the apparatus; the hands of the radiologist are protected by gloves of caoutchouc tissue in which lead salts and barium sulphate have been incorporated. They are 4 millimetres thick, and their weight is considerable, but they can be handled easily enough, and careful experiments have shown that they are absolutely impermeable to the X rays. The operator is thus entirely protected against X ray dermatitis. On the other hand, when the patient is enclosed in the cupboard together with the ampoule the rest of the laboratory is entirely cut off from the X rays, and the radiologist and his assistants are completely under cover. All the experiments have been controlled by means of photographic plates, which have remained unaffected when exposed to these conditions.

The Casier Sanitaire, Tuberculosis, and Cancer.

For many years there has existed at the prefecture of police a docket for every house in Paris, in which every death and every case of notifiable contagious disease is recorded. The system, which was established by M. Juillerat, and is known as the Casier Sanitaire, is beginning to furnish extremely interesting results by pointing out in what houses and quarters certain diseases are endemic. M. Juillerat has noted buildings in which tuberculosis constantly appears in all their successive occupiers, indicating the necessity for the demolition of the buildings. Tuberculosis also is more frequent in those rooms of a house that never get the sunlight. Architects ought always to place sleeping-rooms on the side of the building that overlooks the street, which receives more light and air, but they are usually relegated to the other side, where there will be less dust and noise. The statistics of the Casier from 1909–12 show a progressive, though still insignificant, diminution of pulmonary tuberculosis in Paris. In 1912 the Casier Sanitaire registered 9281 deaths, or 90 less than in 1911, 168 less than 1910, 433 than 1909, and 981 less than 1907 and 1908. On June 1st, 1913, 363 fewer deaths than at the corresponding date of 1912 had been registered, showing no arrest in the diminution. Eleven of the houses marked as tuberculous were demolished in 1912, which raised the total of those destroyed since 1905, and in which altogether 4162 persons had resided, to 61. Further, the Bureau des Services d'Hygiène has imposed upon owners, under the law of Feb. 1st, 1912, the carrying out of the work considered necessary by the Service Technique de l'Hygiène de l'Habitation, and where necessary has prohibited the use of buildings for habitation. At the end of 1912, out of 2758 houses visited 1758 had been put into sanitary condition, and the rest were undergoing the process. In the houses rendered sanitary between March 1st, 1911, and March 1st, 1912 (sheltering 31,391 inhabitants), the mortality had fallen by 1·60 per 1000. Finally, in 1912, in the totality of houses rendered sanitary by order of the administration, the mortality had fallen by 2·39 per 1000 inhabitants from its level previous to administrative control. Unfortunately, there are in Paris six islets (*ilots*) which remain all the time in the same insanitary condition, in spite of all individual attempts. They suffer from an irremediable defect due to the narrowness of the streets and the gloominess of the locality, which only the law of exappropriation for sanitary purposes can do away with. The efforts of the Bureau du Casier Sanitaire in regard to tuberculosis are facilitated by the coöperation of the dispensaries, notably those of Léon-Bourgeois, Albert Robin and Jacques-Siegfried, Omer-Talon and Jouve-Rouve-Taniès, and the preventorium in the boulevard Garibaldi. In regard to cancer, also, the observations of the Casier Sanitaire are very interesting. In 1912 there were registered 2993 deaths, divided between 2841 houses and 25 various establishments. It is worthy of remark that the quarters that have recorded one death from cancer contain 13·34 per cent. of "tuberculosis houses"; those which show two deaths from cancer, 29·32 per cent. of such houses; those showing three deaths, 46·52 per cent.; those with four deaths, 61·19 per cent.; those having five deaths, 80·77 per cent.; and finally, those quarters with six deaths and upwards from cancer were entirely tuberculous. Are there cancer houses as there are tuberculosis houses, and does cancer readily take root where there is tuberculosis? Eloquent figures enable us to speak. During a period of six years, out of 15,114 houses recording deaths from cancer, 498 have recorded at least three, one has even had 11. On the other hand, out of the 498 houses particularly affected by cancer, 252, or more than half, are clearly tuberculous.

Nov. 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Battle of the Clubs.

AN extraordinary meeting of the Aerztevereinsbund and the Leipziger Verband was held in Berlin on Oct. 26th for the purpose of taking measures against the hostile attitude of the sick clubs described in my last letter.[1] The meeting was attended by 458 delegates, representing 384 branches with 21,207 members. The President, Dr. Dippe of Leipzig, stated that the clubs declined to enter into further negotiations not because it was impossible for them to agree with the demands of the Medical Union, but because they wished to destroy the Union and to make separate arrangements with individual medical men. Unfortunately, in three large towns—Berlin, Hamburg, and Dresden—the medical profession, because of the numerous outsiders practising there, has made separate contracts under less favourable conditions than the general demands of the Medical Union, but better than those hitherto existing. In the kingdom of Würtemberg the demands of the Union have already been agreed to by the clubs, but in the other parts of the empire a conflict is imminent. In the course of the debate delegates of various districts reported that complete unanimity existed in the profession, the members of which had pledged themselves over their signatures not to enter into further negotiations with the clubs. It having been proposed that members of the Union should decline to enter into further negotiations with the clubs, and that from Jan. 1st, 1914, they would attend club patients only under the same conditions as private patients, the motion was almost unanimously approved, only four delegates, representing 164 members, dissenting.

The Emperor William Institute for Experimental Therapy.

The Institute for Experimental Therapy in Berlin, built with funds collected on the occasion of the Emperor's jubilee, was formally opened on Oct. 28th in the presence of the Emperor and a large party of distinguished personages, including the Minister of Public Instruction, the President of the Imperial Health Office, the General Staff Surgeon of the Army, Professor Ehrlich, of Frankfort, Professor Waldeyer, of Berlin, Professor Noguchi, of Japan, Professor Harnack. President of the Emperor William Society, and many others. The institute, of which Professor Wassermann is the director, contains a department for serology and bacteriology and a chemical department, the latter being under the special care of Professor Neuberg. The bacteriological and serological department has two large laboratories with six working places, and two smaller laboratories with one working place respectively, besides the private laboratory of Professor Wassermann; the chemical department has a larger laboratory with four working places and several smaller rooms. There are an aseptical operation room for operations on animals, and stables with special arrangements to prevent animals which have been operated upon from pulling off their dressings. The whole institute, consisting of the principal building, the residential building for assistants and guests, and two stable buildings, was finished within the extremely short time of six months. The Emperor was shown over the premises and Professor Wassermann demonstrated the method according to which certain experimental processes were conducted and the ultimate effects obtained in others, including the Wassermann reaction in cases of syphilis and the results of the treatment of malignant growths in mice by selenium. In the neighbouring institute for chemical physics and electro-chemistry a meeting of the Emperor William Society for the Progress of Science was afterwards held, where Professor Hertwig, of the University of Berlin, read a paper on New Problems of Experimental Biology. The Emperor thanked the speaker and also Professor Wassermann, wishing him much success in his work.

Dr. Friedmann's Treatment of Tuberculosis.

On Oct. 25th Dr. Friedmann showed a number of patients treated according to his method in the medical clinic of Professor Kraus in the Charité Hospital in Berlin. Professor Kraus stated that some remarkable instances of improvement had been observed, and that hitherto no harm had been done to the patients by the injections. Dr. Friedmann finally declared that he was now willing to deliver his remedy to the medical profession for general use. According to the *Berliner Klinische Wochenschrift*, where Dr. Friedmann has described his procedure, the remedy is sold in four forms, namely: No. 1, green ampulla, containing 0·5 cubic centimetre of strong concentration; No. 2, a blue ampulla, containing 0·5 cubic centimetre of weak concentration; No. 3, a yellow ampulla, containing 1·0 cubic centimetre of strong concentration; and No. 4, a red ampulla, containing 2·0 cubic centimetres of strong concentration. Dr. Friedmann distinguishes between four different kinds of injection—namely, an intramuscular injection with No. 1 solution; a simultaneous intravenous and intramuscular injection with No. 2 and No. 3 solutions; an isolated intravenous injection with No. 2 solution; and intrafistular or intramuscular injection with No. 4 solution. The No. 1 intramuscular injection is indicated in slight cases of pulmonary tuberculosis and in very severe cases complicated by cavities and mixed infection; also in lupus. A second simultaneous injection with No. 2 and No. 3 respectively must not be made in lupus sooner than eight weeks after the first injection, and only when the healing process makes no further progress. The simultaneous injection with No. 2 and No. 3 is indicated in latent surgical tuberculosis of the bones, tendons, and glands, and in tuberculosis of the genitals and intestines, and finally in tuberculosis of the lungs when dyspnœa is a prominent symptom. In from five to nine hours after the simultaneous injection pyrexia usually develops, with headache, nausea, and vomiting, together with increase of cough and discharge; these symptoms usually disappear within a few days; no harm has been done by these symptoms in more than 1000 injections of that kind. The isolated intravenous injection is indicated when the infiltration at the site of the intramuscular injection begins to swell and to become painful. In this way a suppuration is almost absolutely avoided, and a rapid decrease of the infiltration is produced. In tuberculosis of the lungs the first dose is 0·2 cubic centimetre, which must be injected into the muscles; the second injection must not be made sooner than eight or ten weeks later, and only when the first injection has been absorbed and the healing process

[1] THE LANCET, Nov. 1st, 1913, p. 1283.

makes no farther progress. When after the second injection, 10 or 12 weeks after the beginning of the treatment, no remarkable improvement has taken place, a simultaneous injection is indicated which usually produces a remarkable improvement. If necessary a fourth injection may be made after four months. In fistulæ of bones and joints the first injection must be made with the No. 4 solution. The principal rules for the treatment are that the second injection must not follow the first too early, never before the first infiltration has been absorbed, and never as long as the healing process is still advancing. The remedy must never be used later than 48 hours after the date marked on the bottle.

Foreign Lunatic Paupers.

According to a recent agreement between the British and German Governments concerning lunatic paupers a German lunatic pauper who has been admitted into a British lunatic asylum at the public expense must be repatriated on the request of the British Government to that effect, provided that he has not been in Great Britain longer than 14 months. A similar course will be taken by the German Government in the case of British paupers admitted into German lunatic asylums. The patient must, however, be repatriated only after his home Government has consented to receive him and has specified the place where he is to be delivered to the authorities of his home Government.

Nov. 11th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The National Congress of Pædiatrics.

THIS Congress was held at Bologna from Sept. 21st to 26th. The principal subjects discussed were Disturbances in the Nutrition of Breast-fed Infants, Glands with Internal Secretions in Relation to Infantile Pathology, and Vaccination against Small-pox. On the second subject Professor Simonini and Professor Cattaneo presented their report in a volume of 400 pages. The interest of the third subject was mainly supplied by the presence of Professor Ruata, a well-known opponent of vaccination, who urged: (1) the hypothetical nature of vaccine and the failure to demonstrate its identity with the organism causing small-pox; (2) the failure to obtain immunity by vaccination; and (3) the needlessness of vaccination when recourse can be had to the remedy of isolation. In the ensuing discussion a great point in favour of vaccination was made of the fact that 74 out of 80 English insurance companies insist on vaccination in the applicants for life policies, and the final vote, passed with but three dissentients, expressed the confidence of the members of the Congress in Jennerian vaccination, with the hope that the Government would undertake the manufacture of the vaccine and insist on the scrupulous observance of the law of compulsory vaccination.

Proposed Medical Week.

The large number of medical congresses being held in different cities of Italy at this time of the year has aroused the attention of the profession to the great waste of time, energy, and money involved. Congresses at Parma, Milan, Siena, Turin, Genoa, and Naples, within the space of a month make it impossible for the average medical man to take advantage of such gatherings. It is now proposed that at stated intervals of, for example, two years, there should be a medical week in some city in the centre of Italy, and that all the congresses should be held contemporaneously during the week.

Nursing Reforms.

I have on various occasions in these notes drawn attention to the growing conviction in Italy of the need of improvement in the nursing service of the hospitals and the realisation of the advantages of the employment of women in this service. The proposed unification of the schools for midwives and those for nurses promises a practical solution of the problem. There are schools for midwives in every important centre. It is proposed that the course should be lengthened to three years and the special instruction in midwifery be given in the final year to those who have already taken their diploma in general nursing. This should ensure efficient nursing either in sickness or childbirth and at the same time raise the professional and social status of the midwives.

An Illiterates' Election.

The recent general elections, the great excitement of the past few weeks, have more than a political interest. This has been the first occasion for the exercise of the universal manhood suffrage recently conceded in this country. As a very large proportion of the voters, more than 75 per cent. in some districts, can neither read nor write, the expedient of emblems has been adopted. Each candidate has his own emblem, as, for example, a lion, an aeroplane, or his own portrait. When the voter enters the polling booth the president of the section hands him an envelope and a number of ballot papers, upon each of which is printed the name of one candidate and his emblem. The voter retires into a kind of closet, much like a telephone cabinet, where he chooses the ballot paper of the candidate for whom he means to vote, puts it in the envelope and seals it up; he then returns with it to the president, who deposits it in the urn. The plan has answered admirably, for very few votes were spoilt. The new electors, however, showed but slight interest in the exercise of their newly acquired privilege. The percentage of voters who came to the poll was certainly under 50. The Socialists were able to bring up greater numbers than the other parties, and have largely increased their representation in the Chamber. One of the principal planks in their platform was opposition to the war in Tripoli. The election campaigns were also to a great extent conducted pictorially for the benefit of the illiterates, and the rejoicings of the victors in Florence must have reached the intelligence of the same class when some thousands of the Socialist party passed by night in procession through the streets with torches and chanting funeral dirges behind a mock hearse with the emblems of their defeated rivals.

Nov. 11th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Imre Réczey.

AFTER a long illness Imre Réczey, professor of surgery in our University, died on Nov. 1st in his sixty-seventh year. Both as a surgeon and a teacher he held a pre-eminent position. During his professorship, lasting 21 years, a whole generation of young medical men received their training from him. He had great success also as a teacher

of military surgery. Since 1895 he was president of the Interhospital Association. In 1898 King Francis Joseph conferred on him the Third Class of the Order of the Iron Crown. His literary works were read beyond the borders of Hungary, several of them having been translated into German. His best known work was on the subject of the malignant tumours of the bones, and was translated into German and French.

Cholera in Hungary.

The official gazette of the Ministry of Public Hygiene (Ministry of Internal Affairs) publishes the following report on the occurrence of cholera in Hungary. The first of the recent series of cases declared itself on July 19th at Temessziget, and was soon followed by four others. Afterwards for about two weeks there were no fresh cases of cholera notified. On August 4th one sailor on the ship *Nera*, in harbour at Titel, fell ill with cholera. Independently of this man isolated cases occurred on August 11th in the same county at Kevevara, and in the neighbouring county in Ujvidék. During the first few days of September, near the Galician border in the county of Bereg, several cases were reported. The disease spread along the river Latoreza. In 26 villages the number of cases amounted to 139, out of which 82 terminated fatally. On Sept. 7th seven cases occurred at three different places in Budapest, but fortunately the disease was checked, so that no more cases were observed. During the first ten days of September fresh cases of cholera occurred near the Roumanian and Servian frontiers. In this time not only the fæces of cholera patients but also those of persons suspected to be suffering from the disease were bacteriologically examined. Until Oct. 10th cholera occurred in 16 out of 64 counties. The number of cases was 549 with 272 deaths. As regards the number of cases of cholera in a single place the greatest numbers were notified in the villages of Szenttamas (43 cases) and Szakalar (42 cases). During the week from Oct. 12th to 18th there were 70 fresh cases reported with 33 deaths.

The Results of the Abderhalden Gestational Reaction.

At a recent meeting of the Budapest Royal Medical Society Dr. Scherer read a paper on the Abderhalden Reaction and the results obtained therewith. He said that the two methods suggested by Abderhalden did not work equally well. The optical method gave very precise results, but had some drawbacks, the principal one being that the production of the necessary placenta peptone was very difficult and required special skill. A polarising apparatus had also to be provided. The dialysing method was much easier. Dr. Scherer gave a practical demonstration of the method, and called the attention of the members to the principal sources of error. In his opinion fallacious results were to be attributed to faulty manipulation rather than to the failure of the method. He acknowledged, however, that this reaction was not yet quite reliable, and it was to be hoped that improvements would be made rendering it as perfect a method as the optical one.

Death of Professor Otto de Schwartzer.

The Hungarian medical profession has suffered a great loss by the death of Professor Otto de Schwartzer, the well-known psychiatrist. He had an attack of apoplexy as he sat at his writing desk preparing the annual report of the Red Cross Society, of which he was the president. He was in the sixtieth year of his age, having been up to the last in the full enjoyment of vigorous health. He was not only the leader of the Hungarian alienists, but an authority on general public hygiene, and active in upholding the rights and position of the medical profession. His Majesty King Francis Joseph rewarded his merits by conferring upon him and his lawful offspring a title equivalent to that of a baronet in the year 1904.

Nov. 8th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Bogus Medical Degrees.

THE Government of India has circularised all local governments to give their views as to an All India Act for the registration of medical degrees or for each province to have its local Act, and the local governments are now receiving the views of the more important medical men in India. It was to be expected that a certain amount of opposition would be given. The secretary to the British India Association, Calcutta, has sent a protest to the Bengal Government. Briefly, the association's views are as follows. They note the registration will exclude homœopaths, kabirajes, hakims, vaids, and those carrying out the Yunnani system of medicine. They put medical degrees not officially recognised into two classes—viz., (1) those of foreign origin, and (2) those given by private institutions. With respect to private institutions, they contend the degrees given are not "bogus," as those qualifying have to go through a medical course, even if it be not regarded as of high standard, and as their nature is well known they do not deceive anybody. They say that these institutions do useful work in providing a class of men much wanted in this country in view of the small output by colleges, and that they are preferable to quacks. They are willing to concede some control, and submit the standard should not be raised too high. The improvement of the institutions should be gradual. Finally, they are doubtful if the proposed measure will secure the desired result. Medical registration is very necessary, but there are obvious difficulties to be overcome.

The All India Sanitary Conference.

The India Sanitary Conference, which is to be held at Lucknow in the cold weather, will be a thoroughly representative one, and a large gathering of experts is assured. Captain Needham, health officer of Simla, is to be placed on special duty for three months in connexion with the arrangements for the conference.

Chinese in Calcutta.

It is only in their homes in the by-lanes of Bow Bazaar that one gets a glimpse into the life of the Chinese in Calcutta. They, like their countrymen the world over, are an industrious and thrifty people. Probably this accounts for their triumph over the Indian labourer, as the latter is, even when hardworking, not prudent as far as spending his earnings go. The houses in which the Chinese live also furnish an object-lesson to the Indian labourer. Even where a room is oppressively overcrowded there is not the same disregard for cleanliness as in an ordinary Indian labourer's home. Within the past few years the number of opium

dens in Calcutta has decreased, and it seems that the Chinese in Calcutta look down upon the opium habit.

The Cocaine Habit in Calcutta.

It is gratifying to observe that in dealing with a cocaine case which came before him recently at Calcutta the presiding judge made some very pertinent remarks on the gravity of the offence of illicit trading in the drug. A woman who had been convicted by the Second Presidency Magistrate and sentenced to three months' imprisonment applied for a rule to show cause why the conviction and sentence should not be set aside. This application was, however, refused, and the learned judge, in announcing the decision of the Court, remarked: "These cocaine cases have to be dealt with strictly. Once the case is proved the punishment ought to be deterrent." The trouble, however, is that the maximum punishment is only three months' imprisonment, and until the law is strengthened the miscreants who are responsible for the traffic will not be deterred from carrying on their operations.

The Women's Medical Service.

The grant of an annual subvention of 1½ lakhs of rupees towards the establishment of a Women's Medical Service for India, as a development of the Countess of Dufferin's Fund, is a step in the right direction, but only a step. There is a great hiatus between provision for 25 medical women and the scheme submitted last year for 50 doctors and 60 assistants, the cost of which was estimated by Sir C. P. Lukis at Rs. 5 lakhs per annum. Nor would anyone pretend that 50 doctors and 60 assistants could perform a tithe of the medical work which is now left undone among the millions of women in India. It is not to be imagined for one moment, therefore, that the project which is now announced satisfies the needs of the country or removes the demand upon private philanthropy. It will, however, serve a useful purpose in indicating the lines upon which future efforts may be developed.

Vaccination in Bengal.

Perhaps one of the most satisfactory features in the history of sanitary efforts in India has been the gradual increase of vaccination. The terrible scourge of small-pox has to a great extent yielded to this prophylactic treatment. Formerly the opposition of the ignorant, fomented by mischievous agitators, was very great, and vaccinators were frequently assaulted and driven out of the villages. A peculiarly dangerous form of inoculation with small-pox virus was prevalent in Bengal. Frequently the patient died or became stone-blind, but in those cases where he was only pitted with small-pox for life the preventive was complete, for the patient never got another attack of the disease. Vaccination became unpopular, because revaccination was necessary, and this was considered expensive. Gradually the opposition of the ignorant and prejudiced is disappearing. A good deal of opposition has been due in the past to want of tact and sympathy, as well as to ignorance. Under the careful supervision of civil surgeons and of the sanitary department this opposition is happily passing away. There is in these days a perceptible demand for vaccination, and this once established the feeling in its favour cannot but grow with experience of the results. It is by tackling dreadful scourges, such as small-pox, plague, and malaria, and by dealing tactfully and sympathetically with the prejudices of an ignorant and fanatical population, that Government slowly but surely builds up a link between the people and itself. Every well-wisher of India must view with extreme satisfaction the growing success of the struggle against small-pox.

Infant Mortality in Bombay.

The Bombay Government in its review of the health report of the Presidency for 1912 specially refers to the ratio of infantile deaths to registered births in Bombay city, which was 451 per 1000. The figure does not accurately represent the death-rate among newly born infants, because there has recently grown up a steadily increasing tendency for prospective mothers to go to their villages for the birth of children and to return to the city soon afterwards. The infantile death-rate therefore requires heavy correction, but the Government states its intention to initiate special measures to deal with the matter supplementary to those already taken by the municipality and the sanitary authority.

The City of Cawnpore.

The Government of the United Provinces has appointed an expert committee to consider the best means for the extension of the city of Cawnpore and its improvement.

Anti-Cholera Measures in Madras.

The Government of Madras has drawn up a comprehensive scheme with a view to the prevention of the spread of cholera and to ensuring that the drinking water in village wells shall be kept free from infection. It is said that the sanitary engineer, to whom the inception of the scheme is largely due, has devised a quite inexpensive and simple method in which pumps are to play an important part. The main difficulty which the Government has to face is that these pumps may be objected to on religious grounds. The Government has set apart £30,000 for the purpose, but, in view of possible opposition, will only put the scheme in force as an experiment in certain selected villages.

Antituberculosis Measures in Madras.

At a meeting of the King Edward VII. Memorial Committee it was decided to spend Rs.75,000 upon the creation of a tuberculin institute, and that the balance of money in the hands of the committee, which, with the Government contribution, will amount to about 4 lakhs, be funded for the purpose of supplying money for the upkeep of the institute and its research work. The institute is to be located in the neighbourhood of the Madras General Hospital. As the Government have to decide upon the advisability or otherwise of the removal of the hospital the work of construction of the institute must await the Government's decision on this point.

Oct. 20th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in Sydney.

THE small-pox outbreak in Sydney presents no new features. The disease continues very mild in type and no fatality has been recorded. Although a female patient died in quarantine, after a confinement, it was from causes not connected with the attack of small-pox. Up to the present over 800 cases have been reported, and new cases crop up daily at an average of about 10. Some doubtful

cases have occurred in outlying towns, but on the whole it does not appear that the infection has really spread beyond Sydney. Repeated representations have been made in the Federal Parliament to induce the Government to withdraw the proclamation of Sydney as a quarantine area, but these have been unsuccessful. The promised legislation in New South Wales in the direction of compulsory vaccination has not yet been much in evidence, but the Premier has at last announced the text of the Bill. It provides for compulsory vaccination in infancy and revaccination about puberty, but any parent or any person of age liable may take an oath that they have conscientious objections, so that the measure will be rather farcical. Strenuous effort has been made to get the quarantine embargo removed from Sydney before the spring racing carnival, which begins on Oct. 4th. The New South Wales Board of Public Health drew up reasons why this should be done, and these were submitted at a conference between that body and the Minister for Customs (in whose department quarantine is) and Dr. J. H. L. Cumpston, Director-General of Federal Quarantine. No decision was arrived at, the Minister merely undertaking to consult the Cabinet, and unless some strong pressure is brought on the Premier it is unlikely the request will be granted.

Action against a Medical Man.

A libel action in which a medical practitioner was defendant attracted widespread public attention in Melbourne for some days. The plaintiff was a nurse employed at a private hospital conducted by the defendant at his own residence. Owing to some reprimand from defendant's wife the plaintiff and a junior nurse left their employment summarily. The defendant wrote a letter to the council of the Royal Victorian Trained Nurses' Association, of which the plaintiff was a member, complaining of her conduct, and upon this letter the action for libel was founded. It was alleged, among other things, that the nurse complained of and a junior nurse, who was not a member of the association, had acted unbecomingly in a variety of ways while at the hospital. These allegations both nurses denied. Evidence for the defendant was given by patients who had been in the hospital. The jury were left with 12 questions to answer on the direction of the judge, and of these, after an hour's absence, they found that 10 of the charges were libellous, and that they were not true in substance and fact. They found that the remaining two charges were true in substance and fact. They found also that the charges were malicious, and gave a verdict for £200. Judgment was given for this sum, with costs, to be taxed. A stay of proceedings for seven days was granted.

Commonwealth Pensions.

Australia has a population of something slightly over 4,000,000. What a financial burden these are carrying in old age and invalid pensions is shown by the following official figures laid on the table of the House of Representatives and covering the year ending June 30th. The Commonwealth commenced to pay old age pensions on July 1st, 1909, while that portion of the Act which authorised payment to women on attaining the age of 60 years came into operation on Dec. 15th, 1910. During the last 12 months 14,417 claims were received from all parts of Australia, including 5099 from New South Wales and 4638 from Victoria. In all 11,304 applications had been approved, while 1663 were awaiting determination at the end of the last financial year. On June 30th there were 82,943 pensions in operation, or 3872 more than at the same date 12 months before. The total amount paid in 26 fortnights was £2,449,434 for old age and invalid pensions.

Personal.

Dr. C. S. Ryan has retired from his position as surgeon to the Melbourne Hospital owing to having reached the age-limit. He was appointed assistant surgeon 34 years ago, and has acted continuously on the surgical staff ever since. Dr. Ryan is principal medical officer of the Victorian Military Forces and holds the rank of colonel. He saw service as a young man with the Turkish army inside Plevna during the famous siege of the Russo-Turkish war. He is extremely popular with all classes of the community, and on the occasion of his leaving the Melbourne Hospital for the last time the students and a number of old pupils formed a double line from the hospital to the gates and cheered their old teacher heartily as he passed between the ranks. Dr. Ryan is a native of Victoria, but a graduate of Edinburgh University.

Obituary.

The death is announced in Sydney of Mr. H. Critchley Hinder, one of the leading surgeons of that city. Mr. Hinder was surgeon to the Prince Alfred Hospital and a graduate of Sydney University. He was only 48, and had been in bad health for some months.

Oct. 3rd.

Obituary.

MATHIEU JABOULAY, M.D.,

PROFESSOR OF CLINICAL SURGERY AT THE UNIVERSITY OF LYONS.

IN the fearful railway disaster at Melun a very brilliant and distinguished French surgeon met his death under the most distressing circumstances. Professor Mathieu Jaboulay was travelling to Paris in the train which was wrecked at Melun to preside over the Concours d'Agrégation. This Concours, which had begun early this year, had been cancelled by the Conseil d'Etat for some informality, and it became necessary, therefore, to hold it again. In the same train were several other medical men also going to Paris for the Concours, but Dr. Jaboulay alone was not to be found after the accident. He was in the carriage into which the locomotive and its tender crashed with terrific force. His body remained buried in the wreckage, and was burnt up by the fire which broke out immediately. Even his remains could not be identified, although the Faculty of Lyons sent on by express train his pupil, Dr. Patel, to endeavour to establish the identification in some way. It was only by his watch, which was found beside a mass of ashes, that the horrible catastrophe was established beyond question.

Dr. Jaboulay, who was professor in the surgical clinic of the Faculty of Medicine of Lyons, was one of the most brilliant surgeons of the Lyons School, where he carried on the traditions of Ollier and Poncet. He was born on July 3rd, 1860, at St. Genis-Laval. He had a brilliant medical career. In 1884 he was appointed prosector at the Faculty of Medicine at Lyons and in 1886 became head of the anatomical department, being then only 26 years old. He was appointed surgeon to the

hospitals in 1896 and professor of clinical surgery in March, 1902. He was a very learned man, and endowed with remarkable surgical facility and courage. He worked out the treatment of goitre by exothyropexy, and that of exophthalmic goitre by division of the sympathetic. He devoted much attention to the anastomosis of vessels, and lately had turned himself very energetically to the study of cancer. He was a man of the highest capacities and always interested in regard to novelties. Among his pupils was Alexis Carrel, now of the Rockefeller Institute, New York, who delights to acknowledge his indebtedness to Jaboulay for his first initiation into science.

Among Professor Jaboulay's published works may be mentioned those on the "Microbe of Acute Osteomyelitis" (1885), the "Relations of the Optic Nerves with the Central Nervous System" (1886), the "Surgery of the Great Sympathetic and the Thyroid Body" (a number of his original articles collected and published in 1900 by Dr. Etienne Martin), and the "Surgery of the Nervous Centres, the Viscera, and Limbs" (1902). The appalling circumstances of his death accentuate the grief of the profession over his loss.

HENRY WALTER KIALLMARK, M.R.C.S. ENG.,

SURGEON-LIEUTENANT-COLONEL, ARMY MEDICAL RESERVE.

WE regret to announce the death in the last week of October of Lieutenant-Colonel Henry Walter Kiallmark at Ditchling, Sussex, in his eighty-first year. He received his medical education at University College Hospital, and qualified as a Member of the Royal College of Surgeons of England in 1855. After leaving University College Hospital, where he was house surgeon, he spent the early part of his professional career abroad, and became attached to the Ottoman army as a staff-surgeon. He then returned to England and for some 25 years was a well-known general practitioner in Kensington. His interest in military matters, however, was always keen, and the volunteer movement in the county of Buckinghamshire owed much of its prosperity to his active work. He served in the Royal Bucks Hussars as surgeon, retiring with the rank of surgeon-lieutenant-colonel, and he also held a commission in the Army Medical Reserve. He was a member of the Harveian, Pathological, Obstetrical, and Royal Medical and Chirurgical Societies, and at one time vice-president of the Metropolitan Counties Branch of the British Medical Association. For some time after his retirement from professional work he continued to live in Kensington, and it was only a few years ago that he took up his residence at Hove, leaving that place for Ditchling in August last.

He took much interest in Epsom College and the Royal Medical Benevolent Fund on the committees of which he served. A man of kindly disposition and sound judgment he attracted many friends, and his influence was not lessened by his retiring disposition.

He was buried on Oct. 27th at Kensal Green Cemetery, the coffin being draped with the Union Jack. A large number of relatives and friends attended the funeral, including Colonel the Hon. Harry Lawson, M.P., Major Coningsby Disraeli, and Lieutenant-Colonel C. W. Cole, representing the Royal Bucks Hussars, and Mr. J. Bernard Lamb, secretary of Epsom College.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. G. Cantarano, *privatdocent* of medical pathology in the University of Naples.—Dr. Edwin Klebs, whose death was mentioned in last week's issue, was an eminent pathologist and bacteriologist, whose tubercle and phthisis serums under the titles of tuberculocidin and antiphthisin have been a good deal discussed. He seems also to have been the first to make use of cold-blooded animals in the preparation of bactericidal fluids. He was born in Königsberg, and studied medicine there. His first professorship was in Bern, and he afterwards held chairs in Würzburg, Prague, Zürich, and the Rush Medical College of Chicago. For the last 20 years he had been in Europe, and it was in Bern his death occurred. He was 79 years of age.—Dr. Charles McBurney, of New York, whose name is well known in England and on the continent in connexion with the diagnosis of appendicitis. His reputation as a consulting and operating surgeon in the United States was very great. He was an honorary Fellow of the Royal College of Surgeons, Edinburgh, and a member of many continental medical societies. As a clinical teacher, too, he was very popular and greatly respected. He was professor of surgery in the New York College of Physicians and Surgeons, and surgeon to a number of hospitals. His death is said to have been due to cardiac mischief, perhaps aggravated during a shooting expedition in Maine from which he had just returned. He was 68 years of age.—Dr. William Wathen, professor of midwifery and gynæcology in the University of Louisville.—Dr. Charles E. Michel, formerly professor of ophthalmology in the Missouri Medical College, St. Louis.—Dr. W. Lindow, of Prenzlau, sanitary privy councillor.

ROYAL SANITARY INSTITUTE.—A provincial sessional meeting of this institute will be held at Swansea on Nov. 21st, at 6.30 P.M., in the Free Library, Alexandra-road. A discussion will take place on Open-air Education and Sanitation, to be opened by Dr. Thomas Evans, medical officer of health and school medical officer, Swansea, and a Description of the Swansea Town Planning Scheme will be given by Mr. George Bell, borough surveyor, Swansea. General discussion is invited. A number of visits have been arranged for the following day. Tickets for admission of visitors may be had on application to Dr. Thomas Evans, public health department, 5, Prospect-place, Swansea, who is acting as the local honorary secretary of the meeting; and of the secretary of the Institute, 90, Buckingham Palace-road, London, S.W.—The British Columbia branch of the Royal Sanitary Institute held its first congress at Victoria, Vancouver Island, the capital of the province of British Columbia, on Oct. 22nd, when it held a joint session with the Association of School Trustees. Dr. Home (Victoria) explained the work of the Royal Sanitary Institute, Miss Alice Ravenhill (Shawnigan Lake) gave a much appreciated address on Six Points in School Hygiene, Dr. Wasson (school medical officer, Victoria) read a paper on Physical Defects Arising Before School Age, and Mrs. Peter MacNaughton (of the Vancouver School Board) spoke on Health as an Asset to the Student. At the evening meeting, the Bishop of Columbia, Dr. J. C. Roper, in the chair, Miss Ravenhill gave a most interesting account of the Development of Sanitary Protection through the Ages, and spoke also of the Sanitary Law of British Columbia; and Dr. Home read a paper entitled "Why Children Die," pointing out that these deaths were largely preventable. This is the first sanitary congress held in British Columbia, another being held at Vancouver on Oct. 25th. The members of the institute in Vancouver did good work last winter in training sanitary inspectors even before they were organised.

Correspondence.

"Audi alteram partem."

THE ETIOLOGY OF BONE AND JOINT TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—You published in your issue of Oct. 11th an abstract from the *Deutsche Medizinische Wochenschrift* of a paper by Professor Dr. B. Moellers on the Etiology of Bone and Joint Tuberculosis. The article dealt more especially with the type of organism found in these diseases. Dr. Moellers has seen fit to subject to criticism certain work which I have lately published, and I feel it incumbent upon me to reply to these criticisms.

The article which Dr. Moellers criticises appeared in the *Journal of Experimental Medicine*, Vol. XVI., No. 4, 1912, p. 432. It dealt with the type of organism in 70 cases of bone and joint tuberculosis operated on in the Royal Hospital for Sick Children, and the result of the investigations showed that 58 per cent. were bovine and 42 per cent. human in origin. The acme of Dr. Moellers's criticism is reached when he says that the results published in the *Journal of Experimental Medicine* should not be accepted "until the reasons for these results, differing so widely from all other authors, are made perfectly clear."

Dr. Moellers's original article is a short one, and gives little detail of the methods by which his investigations were conducted. Only 12 cases were personally investigated, the results of the other 163 cases being collected from the literature of the subject. The method he employed in differentiating the organism was the injection subcutaneously into rabbits of 10 mgm. of the culture. He apparently questions the value of the intravenous injection of a much smaller amount, for he says: "Whether Fraser has established another standard than other authors by making use of his intravenous rabbit inoculation cannot be determined, because he does not communicate his post-mortem protocols." The test which I have employed in the differentiation of bovine bacilli has been the intravenous injection into a rabbit of standard weight (2000 grm.) of 0·01 mgm. of tubercle culture; a bovine infection has been in every instance followed by a general tuberculosis. I satisfied myself of the value of the test before I put it into routine use, and it was largely employed in the investigation of the British Royal Commission on Tuberculosis. I quote from the Commission Final Report, Part I., pp. 4 and 5:—

> In rabbits generalised tuberculosis ending in death within 5 weeks resulted from the intravenous inoculation of 0·01 or 0·1 of a milligramme of culture of bovine tubercle bacilli. ..... The disease caused in rabbits by intravenous injection is characterised by extensive miliary tuberculosis of the lungs, liver, spleen, kidneys, and other parts of the body. ..... The results obtained by injecting the bovine bacillus into rabbits in the above doses are thus very striking and definite, and taken with the cultural characteristics of the bacillus afford a trustworthy means of recognising the bovine tubercle bacillus.

It is but reasonable to expect that the intravenous inoculation of a small amount of the culture should constitute a much more delicate test than the crude method of subcutaneous injections of a much larger amount. There exists, therefore, no ground for the suspicion which Dr. Moellers would throw upon the method of differentiating the organism. Dr. Moellers finds himself at a loss to explain the high proportion of bovine tubercle which the investigation of my cases revealed, and because he cannot do so he thinks it advisable that the results should be excluded from general consideration. Surely this suggestion is as unwarrantable as it is short-sighted. Would it not be better to face the facts and to recognise the explanations which undoubtedly do exist? It is probable that the striking difference between my results and those published by Dr. Moellers may be explained by certain distinctions of child life in this country as compared with those in Germany. This is a possibility which does not appear to have been thought of by continental critics. I take it that there are three factors which are responsible for the remarkably large proportion of bovine infection:—

1. *The age of the patients from whom the material was obtained*—all being less than 12 years. Dr. Moellers says that it is impossible to accept this as the entire explanation, and with that we agree: but it is important in so far as it has a definite bearing upon the other factors to be immediately considered.
2. *Milk infection.*—I expect Dr. Moellers does not realise the absurdly inadequate conditions under which milk control up to the present has been conducted in Scotland and Edinburgh is no exception to the rule.
3. *Milk sterilisation.*—It is quite exceptional for the poorer classes, from which my material has been derived, to boil or pasteurise the milk on which their children are nourished. In this way they contrast unfavourably with the corresponding classes in Germany, and it is by the standard of these latter that Dr. Moellers probably judges.

Now, Sir, I consider that I have satisfactorily shown that the basis upon which my results were founded has been perfectly sound. In my published paper I cited several obvious explanations of the apparent difference between my results and those of others; and if any further proof is required of Dr. Moellers's unwarrantable suspicion, it is this—viz., that the work which I began several years ago has been extended in parallel but different directions by other workers who have obtained results similar and even more striking than my own. Dr. A. P. Mitchell has courteously permitted me to draw attention to his, as yet, unpublished results.

Working on the type of organism occurring in tuberculous glands in children, derived also from the Royal Hospital for Sick Children, Edinburgh, he has found that 90 per cent. of the gland infections are bovine in type.

I am, Sir, your faithfully,

Edinburgh, Nov. 5th, 1913. JOHN FRASER, M.D. Edin.

NATHANIEL ALCOCK MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—Some months ago you were kind enough to insert an appeal for subscriptions in aid of the family of the late Professor Alcock. Owing to his early death he had been unable to make any provision for his family, and it was felt that the most appropriate form of memorial to his memory would be a fund to enable his three daughters and one son to receive an adequate education. A list of subscriptions received to date is given below. Since we desire to close the fund before Christmas, in order that it may be invested and the proceeds applied to the object mentioned above, we should be glad to receive any further subscriptions to the fund as soon as possible. Contributions may be

sent to either of the undersigned. Cheques should be crossed "Alcock Memorial Fund."

We are, Sir, yours faithfully,

E. H. STARLING,
Institute of Physiology, University College, London, W.C.

A. D. WALLER,
Physiological Department, University of London, South Kensington, London, S.W.

THE ACCURACY OF CLINICAL THERMOMETERS.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 8th appears an article headed "Some Experiments with Clinical Thermometers." In this article an account is given of certain experiments with clinical thermometers, in which their accuracy is tested in regard to the variations they record when plunged into water of varying temperatures. Then follows the astounding statement "On the whole, the results show that for practical clinical purposes the thermometers gave fairly accurate readings." I beg to suggest that the results recorded are highly misleading as regards clinical work. The inference to be drawn from the statements made is that the temperature of the body is accurately ascertained by leaving one of the thermometers under discussion in the mouth for a period of two minutes. Such a method only ascertains in an extremely rough manner the temperature of the body, for the thermometer is under totally dissimilar circumstances when in a glass of water to that in the cavity of the mouth. Various clinicians have pointed out the serious errors which arise from this rough and ready proceeding, and the paper in your journal would tend to perpetuate this inaccurate method. I have tried many thermometers (Kew certified), and if they require two minutes in water they need 10–15 minutes in the mouth, unless the mouth has previously been kept closed in a warm room.

Malvern, Nov. 10th, 1913. MARY H. WILLIAMS.

*** Has Dr. Williams noted that in our experiments the conditions of environment of both the standard thermometer and the clinical thermometers tested were precisely the same? Any "dissimilar circumstances of the mouth" would apply equally to the standard thermometer.—ED. L.

To the Editor of THE LANCET.

SIR,—The letter from Dr. J. B. Cook which appeared in THE LANCET of Oct. 4th on the results obtained by testing a batch of clinical thermometers supplied under contract to the St. Giles' Infirmary, Cleveland-street, together with that of Mr. F. A. Hocking a week later, convey a lesson to the medical profession which should be taken to heart. A proportion of medical men in practice do regularly test the clinical thermometers which they buy and use for their patients; but the majority, I strongly suspect, omit this simple but very necessary act of precaution. Now that attention has been drawn to the point by the letters in question, it may be hoped that practitioners will take rather more trouble over this matter than most of them have been in the habit of doing. They may urge that so long as they pay a reasonable price for their thermometers, and buy them from respectable firms, the chance of error is exceedingly slight. That may be and most likely is true; but it is not a sufficient defence, for the consequences of any serious error in the graduation of a clinical thermometer can be so serious as to make the difference between life and death. There is, in fact, reason to believe that British-made thermometers, manufactured and sold at prices some hundreds per cent. cheaper than prevailed a few years ago, are accurate and trustworthy in a very high degree. But all thermometers are not British made, and even with respect to those that are, there is one reservation which must be made. A great many of these so-called "half-minute" thermometers do not really give true readings in that short space of time, though they may be perfectly reliable after longer incubation. As an instance of this may be quoted the following experiments recently undertaken by myself. Three thermometers sold by a well-known British firm at 1*s.* 9*d.* each and two by a British private maker at 2*s.* 6*d.* each were shaken down below 95° and placed under the tongue in the usual way; all five were marked "30 seconds." At the end of half a minute they read respectively 95·2°, 96°, 96·8°, 97°, and 97·4°. They were then incubated again for a full minute, and they then indicated 96°, 96·4°, 97·2°, 97·2, and 97·6°. They were

replaced for a further two minutes, after which four of them read 98·0° and one 97·6°. The clear duty of every conscientious practitioner is obvious—namely, to test every clinical thermometer he buys, in regard both to the accuracy of its graduation and to the time taken in reaching the temperature of the surrounding medium.

I am, Sir, yours faithfully,

Nov. 8th, 1913. PHYSICIAN.

*** These observations agree with the conclusions published in our issue last week. We then wrote: "For really accurate observations the 30 seconds thermometers give, generally speaking, more satisfactory results when they are incubated for more than 30 seconds, and according to the above experiments an incubation of a period of two minutes records the practical truth."—ED. L.

THE MEDICO-PSYCHOLOGICAL CLINIC.

To the Editor of THE LANCET.

SIR,—It has been impossible to ignore the press notices of the inaugural meeting of the Medico-Psychological Clinic. It is distressing to the committee to find that a great deal of misunderstanding has arisen, and we feel bound in justice to ourselves, to the pioneers of psychotherapy, and to the supporters of our movement to dissociate ourselves entirely and absolutely from the occult powers that Lord Sandwich claimed for himself. Lord Sandwich has expressed his sincere regret to the committee for the misunderstanding he has caused, and this terminates his association with the clinic and with the committee.

We profess nothing but ordinary medical knowledge acquired in the ordinary way. We have no gifts or methods not open to every practitioner. It is our belief that the clinic will attract cases of threatened nervous breakdown in a stage at which preventive measures may avert calamity. It will offer a place of study for medical practitioners who wish to acquaint themselves with practical psychotherapy. The whole of the healing art was cradled in superstition. In the minds of many psychotherapy is still tinged with charlatanism, and from this the clinic will help to dissociate it.

We feel sure that the profession will appreciate to the full the difficulties and delicacy of the work we have in hand, the dangers to be avoided and prejudices to be overcome, and we trust that it will join with us in aiding a work which must of necessity be the object of adverse criticism and unavoidable misconceptions in its early stages.

We are, Sir, yours faithfully,

HECTOR MUNRO.
J. M. MURRAY.
JOHN SPENCER.
CONSTANCE E. LONG.

Endsleigh-street, W.C., Nov. 10th, 1913.

THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—The figures below are of some interest if they are like those of others practising amongst the insured. The figures will doubtless expand during the winter months, and I reckon the payment we receive will work out at barely 1*s.* per professional attendance—an inadequate sum. Total acceptances, April 15th, 1078; June 30th, 1136; average per quarter, 1107. For 1107 persons accepted for treatment there were, visits, 187; attendances, 1261. June 30th to Sept 30th: Average acceptances, 1146; visits, 136; attendances, 1164. Total number of persons who have seen me once or oftener since April 15th, 601, or 50 per cent. of total on my list.

I am, Sir, yours faithfully,

Brighton, Nov. 8th, 1913. CHAS. FRASER.

THE NATIONAL INSURANCE ACT AND MEDICAL REFEREES.

To the Editor of THE LANCET.

SIR,—At the recent meeting of the London Insurance Committee, of which a short report appeared in THE LANCET of Nov. 1st, a recommendation of the General Purposes Subcommittee was considered which seems to me to raise questions of much importance.

The proposal was that the services of medical referees should be made available to Approved Societies desiring advice (1) as to whether an insured person was incapacitated as a result of illness or injury which might entitle him to receive or recover any compensation or wages under the Workmen's Compensation Act, 1906, or under the Employers' Liability Act, 1880, or otherwise as provided in Section 11 of the National Insurance Act, or (2) as to whether the insured person was suffering from a disease caused by misconduct in respect of which sickness benefit may be suspended under the provisions of Section 14 (2) of the Act. It was further recommended that the expenditure involved could be met out of the sum of £1000 authorised for the services of medical referees out of the Benefits Administration Fund.

The recommendation, I observe, met with opposition upon the committee, Mrs. Handel Booth moving that it should be referred back, but was accepted by a majority. It certainly appears to tend to impose upon medical referees duties outside those for the performance of which their appointment has appeared necessary and has been generally approved. Moreover, it seems to me that it would bring them into unnecessary contact with the Approved Societies and to constitute them investigators of matters outside the expression of medical opinion upon questions of disease. As I understand the matter, the contract for medical attendance is between the medical man and the Insurance Committee, and the certificate given by the medical man should state with accuracy the nature of the disease from which his patient suffers. It may be necessary or desirable that a medical referee should consider the accuracy of a statement as to the nature of a disease made in a certificate, and it may also be necessary or desirable that an Approved Society should be sure that its funds are not being depleted by a person who, owing to the manner in which his incapacity came about or his behaviour when under treatment, is not entitled to partake of them. It does not, however, follow that a medical referee should be employed to do more than make sure that a medical certificate correctly states medical facts, where *primâ facie* there is ground for suspicion that it does not do so. That the medical man attending a patient should have his attention called to the provisions of Section 11 or Section 14 (2) of the Act in respect of a particular case is not unreasonable. But his explanation or opinion on the question involved should be specifically obtained before a medical referee should be invited to intervene, and the intervention of the medical referee

should be confined within strictly defined limits. I submit that these, where they involve inquiries into the original cause of incapacity and the behaviour of a patient, should not go beyond such inquiries as the medical attendant on the panel might reasonably make in the same direction.

I am, Sir, yours faithfully,

Nov. 6th, 1913. MEDICO-LEGAL.

THE NATIONAL INSURANCE ACT.

THE REVISED REGULATIONS FOR MEDICAL BENEFIT.

WE have received from the Insurance Commissioners a copy of the draft Regulations dated Nov. 7th, 1913, which they propose to make under Section 15 of the National Insurance Act, together with a leaflet (Memo. 185/I.C.) which deals with the method which has been adopted in revising the Regulations for medical benefit and with the arrangements for providing this benefit during the year 1914.

These Regulations, which will come into operation on Jan. 12th next, will shortly be on sale.[1] They take substantially the same form as the original Regulations for medical benefit which came into force last year. The Commissioners state that the revision embodied in these new Regulations was undertaken with a view to the adoption of numerous suggestions made as a result of actual working experience, and for the purpose of simplifying and facilitating administration for all parties concerned. This revision has been completed after consultation with the Advisory Committee.

The Commissioners in the accompanying memorandum draw attention to some of the more important amendments in the revised Regulations, and suggest means by which Insurance Committees may enter into agreement with medical practitioners and pharmacists on the basis of the revised terms of service. It is particularly noted that the new Regulations do not affect the amount available for the remuneration of panel practitioners in respect of their services under the Act. Owing to the great difficulties experienced in the allocation of insured persons and the calculation of payments due to practitioners the Regulations have been modified. Insurance Committees are now relieved of the obligation to attempt such an allocation, while the First Schedule has been amended so as to secure that the "quarterly credit" of each practitioner shall be calculated on the numbers on his list at the beginning of the quarter, thus enabling the preparation of the quarter's accounts to be undertaken soon after the commencement of the quarter.

The system of complete personal allocation having been abolished, an equivalent provision is made for distributing the available funds among practitioners on the panel, in accordance with the right which they respectively assume. By this device panel practitioners are to be credited with additional capitation fees equal in number to the number by which the insured population entitled to medical benefit at the beginning of the quarter exceeds the total number on the practitioners' lists at that date.

The Panel Committees (referred to in our last issue) are to make arrangements in advance for the assigning among doctors on the panel, or some of them, of insured persons who subsequently apply to be assigned; and the method of distribution of the additional capitation fees will take into consideration the responsibility thus placed upon individual practitioners for patients subsequently assigned to them during the quarter.

The memorandum explains the general effect of the changes made in the new Regulations under the heads of Removals and Temporary Residents. The Commissioners claim that the main effect of these changes is in the direction of greater simplicity and uniformity. With regard to complaints, the powers of Insurance Committees have been enlarged in some respects, while panel practitioners will be afforded a general right of appeal to the Commissioners against any decision of an Insurance Committee on a question investigated by the Medical Service Subcommittee. The revision of the First and Third Schedules has involved corresponding changes in some of the actual Forms of Agreement, while clauses have been drawn up so as to meet the widespread desire expressed by medical practitioners, and endorsed by the Advisory Committee, to obviate the need of an appeal to the law courts in case of dispute between a panel practitioner and an Insurance Committee, as well as to meet difficulties due to breaches of the practitioner's Agreement not sufficiently covered by the previous Regulations. The memorandum concludes with suggestions for expediting the arrangements made by Insurance Committees for providing medical benefit for the medical year commencing January 12th, 1914.

[1] Draft Regulations, National Health Insurance (Medical Benefit), England, 1913. Wyman and Sons, Fetter-lane, London, E.C. Price 3½d.

ABERDEEN INSURANCE COMMITTEE.

At a recent meeting of the Aberdeen Insurance Committee a minute of the finance committee was discussed to the effect that the Scottish Insurance Commissioners should be asked whether they would be prepared to sanction an expenditure of £100 annually upon putting into effect Section 60 (1) (b) of the Insurance Act, 1911, which says that an insurance committee "shall make such provision for the giving of lectures and the publication of information on questions relating to health as it thinks necessary or desirable.[1]" Mrs. Ogilvie Gordon and Dr. Forbes spoke in favour of taking action under the section, and dwelt upon the necessity for education in matters of health in order to preserve the well-being of the community; the chairman intimated that the Commissioners had expressed in a letter general sympathy in the proposal, and the meeting was unanimously in favour of steps being taken under the subsection referred to. The question of the choice of a medical attendant by the insured was also discussed. 7700 postcards had been issued to those who had not made their choice, and of these 2633 had been returned, the number of those who after being specially communicated with had selected medical men amounting to 3000. Mr. John Milne, who introduced the report dealing with this topic, said that it was "a matter that interested insured persons very deeply, but they had also recognised that the medical men had their rights in the matter." Apparently the question of distributing without further delay those insured persons who had not felt deeply enough interested to make their choice has not yet been dealt with at Aberdeen, and the report of what had taken place was adopted without it being raised. At

[1] THE LANCET, Nov. 1st, p. 1280.

the same meeting it was stated that the Commissioners, in reply to questions on the subject from the Medical Service Subcommittee, said that in terms of his agreement the insurance practitioner must, at the request of an insured person who was on his list, furnish free of charge such certificates of incapacity as were required to be furnished in connexion with any claim for sickness or disablement benefit made by him in pursuance of the rules of the society of which he was a member. The insurance practitioner should furnish such certificates at the request of the insured person and any certificates necessary to satisfy the society that arrears were not to be reckoned. The practitioner was, of course, not bound to furnish certificates for the purpose of satisfying the employer as to compensation, but he should supply such certificates as were necessary to enable the insured person to obtain an advance from his society pending the settlement of his claim.

BRISTOL INSURANCE COMMITTEE.

At a recent meeting of the Bristol Insurance Committee some interesting figures were given by the chairman with regard to the work of the committee. At Bristol on July 14th there were 120,058 persons entitled to medical and sanatorium benefits. The addition of deposit contributors out of all benefits brought the figure up to 120,343, or about one-third of the whole population, a net increase of 6173 insured persons. Payment to medical men and institutions had been on account of 96,316 persons who had chosen their medical attendants and 11,304 treated through institutions; 12,723 persons had not chosen their medical men, an increase on the figure (less than 10,000) of a few months earlier. The disposal of a sum of £4453 was thus under consideration, and the chairman supposed it would some day reach the hands of the medical profession. He called attention to the disregard of 10 per cent. of the insured to exercise their right of choice, and expressed regret that the system of payment by incidence of sickness was not adopted by the medical profession at Bristol. This would have meant the distribution of the whole of the panel fund quarter by quarter, money would be earned by work done with less clerical work for the Committee and for the medical men, and there would have been no funds left to quarrel about in the future. He did not know whether it was now possible to change their system of remuneration, but he personally would welcome the alteration, and he believed that it would be for the benefit of the insured persons. The payment to druggists for work done and materials supplied was on a more business-like and satisfactory basis than that with regard to medical attendance, and he believed that the payment of fees for treatment accorded would ensure fewer complaints of perfunctory attendance. He described the capitation system as the voting of salaries, each vote being worth 7*s*. a year to its recipient. There were 117 medical men on the Bristol panel, of whom 61 received less than £200 a year, the average earnings of these amounting to £113. One medical man made over £1100 a year and two made over £1000. Half the divisible fund was shared by 26 medical men with an average of £650 per annum. The remainder was divided between 91, who took from £400 a year to a few sovereigns.

A report of the Medical Benefit Subcommittee on the subject of the medical adviser to the committee showed that after consultation with the Medical Service Subcommittee it recommended that the services of Dr. Bertram M. H. Rogers should be continued in this capacity for three months, the terms of service being a retaining fee of £82 10*s*., and that Approved Societies with members in the area be invited not to appoint referees of their own, but to refer all cases through the committee to Dr. Rogers, at a charge of 2*s*. 6*d*. per case referred and 5*s*. per case examined; that medical men on the panel should also refer cases to him; and that the Commissioners be asked to appoint a permanent medical adviser—this to be, perhaps, eventually a whole-time appointment. The scheme referred to had received provisional approval from the Commissioners. The report was adopted.

Information was laid before the committee with regard to arrangements made by the Sanatorium Benefit Subcommittee for the reception of insured persons nominated by the committee at the Royal National Sanatorium, Bournemouth, at a fee of 30*s*. per week for each patient. Seven persons had been sent to this institution, and arrangements were pending for the sending of four more.

A CONFERENCE OF NON-PANEL MEDICAL SOCIETIES.

A conference of non-panel medical associations will be held in London at the Waldorf Hotel, Kingsway, W.C., on Saturday, Nov. 29th, at 3 P.M.

The National Medical Union, with the assistance of several leading London societies, is responsible for convening this meeting. Invitations are being issued to all known non-panel bodies, and the chief object of the conference is the promotion of the federation of non-panel organisations throughout the country. The promoters aim at making the meeting representative of all non-service practitioners, and secretaries of all such associations and all medical men who are not serving under the National Insurance Act are earnestly requested to communicate with the secretary of the Union, Mr. J. Webster Watts, 5, John Dalton-street, Manchester.

On Nov. 6th, at a meeting of the London Medical Committee, which is entirely non-panel, it was decided to send representatives to the Conference of Non-panel Associations. The committee appointed the chairman, Dr. Fred. J. Smith, Dr. Bernard O'Connor, barrister-at-law, and the honorary secretary, Mr. E. Arthur Dorrell, to be the representatives at the conference. A report was received by the committee that non-panel associations had been formed for Lambeth and for Islington and St. Pancras (combined). Also reports of meetings and of the strength of membership were received from Wandsworth, Hampstead, and Lewisham non-panel associations. A letter was received from a medical man in the Wandsworth district, who has unrivalled opportunity of observing the working of the Insurance Act in the poorer districts, showing how thoroughly the insured dislike the Act and the panel system with its restricted choice of doctor, and how "hundreds of panel patients come to me" either because they will not go to a panel doctor or do not wish to repeat the experience. The committee adjourned until Monday next, Nov. 17th.

ENFIELD LOCAL MEDICAL COMMITTEE.

A meeting of the Enfield Local Medical Committee (recognised as consisting of all the resident practitioners in the area) was held on Nov. 7th, and 12 members were present. The Commissioners' Circular 30/1C was considered, and it was resolved to memorialise the Commissioners in favour of the

election of the New Panel Committee for Middlesex by districts. It was decided that nomination papers be signed in favour of Dr. J. Busfield, Dr. R. M. Hall, Dr. H. Distin, Dr. F. W. Foott, and Dr. R. L. Ridge, but in the event of election by districts being sanctioned, and two members only being allowed for Enfield, that then the three latter would withdraw their nominations in favour of Dr. Busfield and Dr. Hall.

The honorary secretary was authorised to send the names of these two practitioners to the medical papers as the official nominees of the Local Committee; also to ask general support for these candidates, and to promise the support of Enfield practitioners to the officially recognised candidates of other Local Committees if in proportion to the practitioners in those districts. Dr. Tresilian, Dr. Busfield, and Dr. Ridge were elected as the medical members of the District Insurance Committee.

THE DEATH OF DR. HORACE DIMOCK.

The inquiry into the death of Dr. Dimock was resumed on Wednesday last by the coroner for the Isle of Ely, Mr. Martin Hall, who said that it had been agreed to adjourn the inquest again until Dec. 3rd, Dr. W. H. Willcox requiring a month to complete his analyses.

Revelations have been made as to the persecution to which Mr. H. C. Meacock and other practitioners had been subjected owing to the position which they considered it due to themselves and their profession to take up; and it has now become apparent to the public, as well as to the medical profession, that the legal action taken against the late Dr. Dimock was an absolutely defensive measure supported and conducted by the police. The statutory Local Medical Committee of the Isle of Ely have passed a resolution recording "entire confidence in the honour of its chairman, Mr. H. C. Meacock, and the other medical practitioners of Wisbech, whose characters have been assailed in a most scurrilous and underhand manner," and extending to them and their wives "most sincere sympathy in their recent undeserved trouble."

The panel remains closed to the Wisbech practitioners, Dr. H. G. Baynes having been appointed in the room of the late Dr. Dimock.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held on Nov. 6th at Caxton House, Westminster, with Sir Francis H. Champneys in the chair.—A number of midwives were struck off the roll, the following charges, amongst others, having been brought forward: Having advised that a case was one in which the attendance of a medical practitioner was required, and a medical practitioner being in attendance accordingly, his instructions were not faithfully carried out as required by Rule E.6. Neglect to take the pulse and temperature of patients, as required by Rule E.13; neglect to wash the patient at any time; not being scrupulously clean, being ignorant of antiseptics and having no proper appliances, as required by Rule E.2. That when attending patients the midwife did not wear a clean dress of washable material, as required by Rule E.1. The bag of appliances was dirty, and had no washable lining. Not keeping the Register of Cases as required by Rule E. 23. Medical aid having been sent for, the midwife neglected to send any notification thereof to the Local Supervising Authority, as required by Rule E. 21 (1). A child suffering from inflammation of and discharge from the eyes, the midwife having explained that the attendance of a registered medical practitioner was required, she did not hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20 (5).

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Giessen:* Dr. Alfred Brüggemann has been recognised as *privat-docent* of Otology and Rhino-laryngology.—*Greifswald:* Dr. Heinrich Gebb, *privat-docent* of ophthalmology, has been granted the title of Professor.—*Hamburg:* Dr. J. F. Wiesinger, surgeon to St. George's Hospital, Dr. Carl Sick, surgeon to the Eppendorf Hospital, Dr. Hermann Wilbrand, ophthalmic surgeon to St. George's Hospital, and Dr. Max Nonne, physician to the Eppendorf Hospital, have been granted the title of Professor.—*Lausanne:* Dr. Taillens, *privat-docent* of medicine, has been promoted to an Extraordinary Professorship.—*Naples:* Dr. Ermanno Cedrangolo has been recognised as *privat-docent* of Medical Semeiology.

MEDICAL MAYORS.—The following members of the medical profession have been elected or re-elected to the mayoral chair: Mr. J. Robinson, L.R.C.P.I., L.R.C.S.I. (Cardiff, Lord Mayor); Mr. Preston King, M.D., B.C. Cantab. (Bath); Mr. S. Hale Puckle, M.B., Ch.M. Edin. (Bishops Castle); Mr. J. Rafter, L.R.C.P.I., L.R.C.S.I. (Bootle); Mr. S. R. Alexander, M.D. Lond. (Faversham), re-elected; Mr. H. Foster Jeffery, M.B., Ch.B. Vict. (Heywood), re-elected; Mr. W. E. L. Davies, M.R.C.S. Eng., L.R.C.P. Lond. (Llanidloes); Mr. Nicholas W. Fairles-Humphreys, M.R.C.S. Eng. (Montgomery), fifteenth time; Mr. J. L. Davies, M.R.C.S. Eng., L.R.C.P. Lond. (Newport, Mon.); Mr. R. Jones Evans, M.R.C.S. Eng., L.R.C.P. Lond. (Pwllheli); Mr. J. Parkinson Atkinson, M.D. Glasg. (Saffron Walden), re-elected; and Mr. A. W. Limont, M.B., C.M. Edin. (Southport).—Mr. F. W. S. Stone was at the municipal elections at Dover returned at the head of the poll in an important ward. He has been chosen as deputy-mayor.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: SCHOOL MEDICAL OFFICERS.—The first meeting of the School Medical Service group of the Society of Medical Officers of Health was held at 1, Upper Montague-street, London, W.C., the office of the society, on Nov. 7th, under the chairmanship of Dr. Alfred Greenwood. Dr. Robert Hughes, of Stoke-on-Trent, was elected chairman, Dr. Armly Ashkenny as honorary secretary, and Dr. C. W. Hutt, honorary treasurer. The committee of the group consists of the above three *ex-officio* members, together with one member from each of the 10 branches of the Society of Medical Officers of Health. The constitution of the group was discussed, and it was decided that all medical officers engaged in the School Medical Service be invited to join; and assistants in the service will have special consideration, for, as pointed out by Dr. A. Bostock Hill, the school medical officer and medical officer of health for Warwickshire, the primary object of the group is to remedy the admitted discontent existing among them rather than among the senior or administrative medical officers, who already have their own groups. Subjects urgently pressing for remedies were fully discussed. The present low salaries of assistants were condemned as very inadequate considering the long, expensive, and arduous professional training, often lasting for ten years, and the responsible, onerous, and the rapidly increasing duties to be performed. It was pointed out that the Board of Education have admitted the inadequacy of salaries of medical officers in their circular letter to local authorities dated August 18th. Even with the promise of increased grants by the board for medical inspection, local education authorities were not likely to increase the salaries of the medical staff to any considerable extent, as desired by the board, unless all assistant medical officers combined in one body and unitedly claimed just treatment from local authorities. The group meeting therefore passed a resolution to the effect that the Society of Medical Officers of Health recommend the British Medical Association to accept no advertisement for a whole-time assistant school medical officer at a less sum than a commencing salary of £350 per annum. The next meeting of the group will be held on Saturday, Dec. 6th, at 2 P.M., at 1, Upper Montague-street, Russell-square, London, W.C. Assistants in the School Medical Service are requested to send their name and address, and anything that may be of interest to the service to Dr. Armly Ashkenny, honorary secretary, Medical Department, Education Office, Council House, Birmingham.

PATHOLOGICAL UNIVERSITY INSTITUTE, BERLIN.—This institution, of which Dr. Goldscheider is the director, has just been considerably enlarged. The clinical department now contains 56 beds, 15 of which are reserved for hydrotherapeutic treatment. In the out-patient department there are now eight assistant physicians.

A PLYMOUTH CENTENARIAN.—John Ryan died at Plymouth on Oct. 29th in his 104th year. He was born at Thurles, Tipperary, on June 24th, 1810, and went to Plymouth in 1851. He was wonderfully active for his age, and until two weeks previously to his death walked to church every Sunday.

A MEETING will be held on Tuesday, Nov. 18th, at 8.30 P.M., at 11, Chandos-street, W., to discuss the position of medical officers in His Majesty's prisons. The chair will be taken by Dr. W. Hugh Fenton. A resolution will be submitted calling upon the Home Office to cease to require the prison medical officers to act under the direction of the lay authorities in professional matters, and to abandon the practice of forcible feeding, which has proved futile, and which is only continued as a punishment.

GLASGOW UNIVERSITY CLUB, LONDON.—The winter dinner of this club will be held at the Trocadero Restaurant, Piccadilly Circus, on Friday, Nov. 28th, at 7.15 for 7.30 P.M., under the chairmanship of Sir William S. McCormick, secretary to the Carnegie Trust. Members intending to be present or to bring guests should give early notice to the honorary secretaries, Dr. David Roxburgh and Dr. Alexander Macphail, at 30, Seymour-street, London, W.

ROYAL SOCIETY OF ARTS.—The society will commence its 160th session on Nov. 19th with an address delivered at 8 P.M. by Colonel Sir Thomas H. Holdich, K.C.M.G. Before Christmas there will be four meetings besides the opening meeting, the subjects and the names of the speakers being as follows: Zoological Gardens, by Dr. Chalmers Mitchell; Perfumery, by Mr. John Umney; Applications of Electricity to Agriculture, by Mr. Thorne Baker; and the Channel Tunnel, by Mr. Arthur Fell. There will be five courses of Cantor Lectures, of which one course consisting of three lectures on the Measurement of Strains in Materials and Structure will be delivered by Professor Coker on Dec. 1st, 8th, and 15th. During the Christmas holidays a course of juvenile lectures on wireless telegraphy will be given by Mr. Howgrave Graham.

ROYAL MEDICAL BENEVOLENT FUND.—At the October meeting of the committee 24 cases were considered and grants amounting to £181 made to 18 of the applicants. Appended is an abstract of the cases relieved:—

Widow, aged 48, of M.R.C.S., L.R.C.P. Practically unprovided for at husband's death 18 months ago, and is endeavouring to support herself by taking boarders. Two daughters, aged 18 and 9, the elder earning 12s. 6d. a week as a clerk, the younger at an institution. Relieved once, £10. Voted £10.—Daughter, aged 61, of late M.R.C.S. Was one of nine children at the death of her father 50 years ago, and for many years supported herself and helped her mother by acting as governess or school matron. Income only a few shillings a week, and is no longer able to obtain remunerative work. Voted £10.—Widow, aged 70, of M.D. Glasgow. Lost her husband six months ago, and finds that owing to depreciation in investments her income will be less than £10 a year. No children or relations able to give permanent help. Voted £18.—Widow, aged 55, of L.R.C.P., L.R.C.S. Edin. Lost her husband a few months ago after an illness lasting several years, during which she supported the family by taking lodgers. Five children, of whom four are still at school and the eldest has just obtained a bursary at a university. Voted £12.—Widow, aged 50, of M.R.C.S. Quite unprovided for at recent death of husband from new growth, but hopes to support herself by obtaining paying guests. Voted £10.—L.S.A., aged 55. Has a very small practice in a London suburb, but has broken down in health and is ordered a holiday which he can ill afford. Voted £5.—Widow, aged 51, of M.D. Edin. Lost her husband some months ago after a long and painful illness which quite exhausted his small savings. Receives 3s. a week from a stepson and takes a lodger. Voted £10.—Widow, aged 46, of L.F.P.S. Glasg. Supported herself for several years after her husband's death as a school matron, but was obliged to give up her post on account of progressive deafness. No income, and dependent on a widowed mother whose means are very small. Asks for assistance to cover the expenses of sending her only son in for the examination for a second mate's certificate. Relieved once, £10. Voted £10.—Daughter, aged 68, of late M.R.C.S. Was a nurse for many years, and now has a pension of £20 a year from another society. Relieved three times, £36. Voted £6.—Widow, aged 73, of M.R.C.S. Receives an old-age pension and slight help from her children, but asks for assistance towards expenses incurred through chronic ill-health. Relieved eight times, £96. Voted £12.—Daughter, aged 51, of late M.R.C.S. Has a small house at a low rent, letting rooms in the summer and making sweets in the winter. Relieved twice, £20. Voted £12.—Daughter, aged 41, of late F.R.C.S. Has a stiff right shoulder-joint, which makes it very difficult to obtain regular and suitable employment. Relieved seven times, £84. Voted £12.—Daughter, aged 54, of late M.R.C.S. Used to be a nurse, but suffers from chronic glaucoma, and is now quite unable to support herself. Slight help from relations. Relieved five times, £45. Voted £10.—Widow, aged 73, of M.R.C.S. Receives an old-age pension and 5s. a week from a charitable society. Relieved once, £12. Voted £9.—Widow, aged 47, of M.D. Assists at a boarding-house kept by a widowed sister, but receives no salary, and asks for help towards small expenses unavoidably incurred for her boy, aged 14. Relieved 14 times, £151. Voted £5.—Widow, aged 64, of L.R.C.S., L.R.C.P. Irel. Has a situation as cook, but finds the work so hard that she is obliged to give it up. Proposes to live with a son earning a small weekly wage and having five children. Relieved once, £5. Voted £12.—Daughter, aged 71, of late M.D. Is an inmate at a Home for Incurables, but has no means to meet small unavoidable expenses. Was an annuitant of this Fund until elected to the Home. Voted £6.—Daughter, aged 58, of late M.R.C.S. Is almost blind and entirely dependent upon a friend and the help given by this Fund. Relieved three times, £22. Voted £12.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ADAMSON, A. F., M.B., Ch.B. Edin., has been appointed Junior Assistant Physician at the Ayr District Asylum.

BRIDGE, JOHN C., F.R.C.S. Edin., D.P.H. Camb., has been appointed a Medical Inspector of Factories.

CARLING, E. ROCK, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Demonstrator of Surgical Anatomy at Westminster Hospital Medical School.

D'ALTON, J., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Banagher District of King's County.

EVANS, ARTHUR, M.S., M.D. Lond., F.R.C.S. Eng., has been appointed Teacher of Operative Surgery and Demonstrator of Surgical Pathology at Westminster Hospital Medical School.

FISHER, E. G., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Registrar and Tutor to the Royal Infirmary, University of Liverpool.

HALL, J., M.B., B.Ch.R.U.I., has been appointed House Surgeon at the Royal Victoria Hospital, Belfast.

HENDERSON, JOHN, M.D., Ch.B. Glasg., F.R.F.P.S. Glasg., has been appointed Lecturer-Examiner in Clinical Medicine in the University of Glasgow.

MOXON, FRANK, M.B., B.S. Durh., has been appointed Honorary Ophthalmic Surgeon to the St. Marylebone General Dispensary.

NIX, R. E., M.B., B.C. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Chatteris District of the county of Cambridge.

ORR, VIVIAN B., M.B., B.S. Melb., has been appointed Lecturer on Anæsthetics at Westminster Hospital Medical School.

SLOAN, J. F. M., M.B., Ch.B. Glasg., has been appointed Senior Assistant Physician at the Ayr District Asylum.

SWAINSON, J. M. G., F.R.C.S. Eng., has been appointed Joint Tutor in Surgery at Westminster Hospital Medical School.

TURNER, WILLIAM, M.S., M.B. Lond., F.R.C.S. Eng., has been appointed Lecturer on Surgery at Westminster Hospital Medical School.

TYRRELL, W., M.B., B.Ch.R.U.I., has been appointed House Surgeon at the Royal Victoria Hospital, Belfast.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARGYLE AND BUTE ASYLUM, Lochgilphead.—Assistant Medical Officer, unmarried. Salary £200 per annum, with apartments, board, and laundry.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—House Physician, also House Surgeon, for six months. Salaries at the rate of £75 per annum, with board, residence, &c.

BETHNAL GREEN INFIRMARY AND WORKHOUSE, Cambridge Heath, E.—Second and Third Assistant Medical Officers. Salary at rate of £120 and £100 per annum respectively, with board, residence, and washing.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES.—Clinical Assistant for three months. Salary at rate of 52 guineas per annum.

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—House Surgeon. Salary at rate of £100 per annum.

BIRMINGHAM, ROMSLEY HILL SANATORIUM FOR CONSUMPTIVES.—Assistant Resident Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and laundry.

BRECON, BRECONSHIRE COUNTY COUNCIL.—County Medical Officer of Health and County School Medical Officer. Salary £500 per annum.

BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—House Physician, unmarried. Salary £100 per annum, with apartments, board, and laundry.

BRISTOL ROYAL INFIRMARY.—House Surgeon for six months for Throat, Nose, and Ear. Salary £75 per annum, with board, apartments, and laundry. Also Dental House Surgeon for six months. Salary at rate of £100 per annum, with board, apartments, and laundry. Also Honorary Assistant Physician.

BURY AND DISTRICT JOINT HOSPITAL BOARD.—Assistant Medical Superintendent. Salary £200 per annum, with board, washing, and lodging.

CAMBERWELL INFIRMARY AND CHILDREN'S HOMES.—Assistant Medical Officer. Salary £180 per annum, with apartments, board, and washing.

CAMBRIDGESHIRE COUNTY COUNCIL.—Tuberculosis Officer. Salary £300 per annum.

CARMARTHEN, JOINT COUNTIES ASYLUM.—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, &c.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £100 per annum, with board, lodging, and washing.

CHESTER GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with residence and maintenance.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

CORNWALL EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £250 per annum.

DERBY, DERBYSHIRE ROYAL INFIRMARY.—House Surgeon. Salary £100 per annum, with apartments, board, &c.

DINAS MAWDDWY BOARD OF GUARDIANS.—Medical Officer, &c. Salary about £110 per annum.

DORCHESTER, COUNTY ASYLUM.—Third Assistant Medical Officer. Salary £200 per annum, all found.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, and laundry.

DOWN COUNTY COUNCIL.—Assistant Tuberculosis Medical Officer. Salary at rate of £350 per annum.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £100 per annum, with residence, board, and washing.

EASTERN DISPENSARY, Leman-street, E.—Resident Medical Officer. Salary £120 per annum, with residence and attendance.

EAST SUSSEX COUNTY COUNCIL EDUCATION COMMITTEE.—Junior Assistant School Medical Officer. Salary £250 per annum.

GATESHEAD ASYLUM, Stannington, Northumberland.—Assistant Medical Officer, unmarried. Salary £220 per annum, with rooms, board, and laundry.

GATESHEAD UNION, WHINNEY HOUSE ESTABLISHMENTS AT SHOTLEY BRIDGE FOR AGED AND INFIRM AND OTHER POOR PERSONS.—Resident Assistant Medical Officer. Salary £250 per annum, with apartments, rations, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, London, N.—House Physician for six months. Salary at rate of £40 per annum, with board, residence, and laundry. Also Surgeon to Out-patients.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

HASTINGS, EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary at rate of £80 per annum, with residence, board, and washing.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida-vale, W.—Two Assistant Physicians.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Surgeon to Out-patients.

HULL ROYAL INFIRMARY.—Casualty House Surgeon for six months. Salary at rate of £80 per annum, with board and lodging.

INDIA OFFICE, London, S.W.—Dentists for British Troops in India.

ITALIAN HOSPITAL, Queen-square, W.C.—House Surgeon for six months. Salary £60 per annum, with board and residence.

KELLING SANATORIUM, Norfolk.—Assistant Resident Medical Officer, unmarried. Salary £70 per annum, with board, lodging, and laundry.

KENSINGTON AND FULHAM GENERAL HOSPITAL, Earl's Court, S.W.—Dental Surgeon.

LEICESTER BOROUGH MENTAL HOSPITAL, Humberstone.—Junior Assistant Medical Officer, unmarried.

LIVERPOOL, CITY OF.—Assistant Tuberculosis Officer. Salary at rate of £400 per annum.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—House Surgeon. Salary at rate of £80 per annum.

LONDON FEVER HOSPITAL, Liverpool-road, N.—Assistant Resident Medical Officer. Salary £150 per annum, with board and residence.

LONDON LOCK HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing. Also House Surgeon to Female Hospital, Harrow-road, W. Salary £100 per annum, with board, residence, and washing.

MACCLESFIELD GENERAL INFIRMARY.—Senior House Surgeon and Junior House Surgeon. Salary £100 and £80 per annum respectively, with board and residence.

MAIDSTONE, KENT COUNTY ASYLUM.—Fourth Assistant Medical Officer, unmarried. Salary £200 per annum, with quarters, attendance, washing, &c.

MANCHESTER, BAGULEY SANATORIUM FOR TREATMENT OF TUBERCULOSIS.—Assistant Medical Officer, unmarried. Salary £200 per annum, with board and residence.

MANCHESTER, MONSALL FEVER HOSPITAL.—Third Medical Assistant. Salary £100 per annum, with board, lodging, and washing.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Assistant Surgeon.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.—Resident Medical Officer for six months. Salary at rate of £80 per annum, with board, residence, and washing.

NEW HOSPITAL FOR WOMEN, Euston-road.—Female House Physician, Two House Surgeons, and Obstetric Assistant for six months. Also Clinical Assistants for Out-patient Department and Assistant Pathologist.

NEWCASTLE-UPON-TYNE AND NORTHUMBERLAND SANATORIUM FOR CONSUMPTIVES, Barrasford, North Tyne.—Resident Medical Officer, unmarried. Salary £250 per annum, with board, residence, and laundry.

NEWCASTLE-ON-TYNE DISPENSARY.—Resident Medical Officer. Salary £250 per annum, with apartments, &c.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Resident Surgical Officer, unmarried. Salary £100 per annum.

OLDHAM ROYAL INFIRMARY.—Third House Surgeon for six months. Salary at rate of £80 per annum, with residence, board, and laundry.

OXFORD COUNTY ASYLUM, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing.

PADDINGTON INFIRMARY.—Second Assistant to Medical Superintendent of Infirmary and Medical Officer of Workhouse. Salary at rate of £140 per annum, with board, lodging, and washing.

POOLE, BOROUGH OF.—Medical Officer of Health. Salary £400 per annum.

POPLAR TRAINING SCHOOL, Hutton, Essex.—Visiting Dentist. Salary £60 per annum.

PORTSMOUTH ROYAL HOSPITAL.—House Physician for six months. Salary £80 per annum, with board, &c.

RICHMOND, SURREY, ROYAL HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board, apartments, and washing.

ROUSAY AND EGILSHAY, PARISH OF.—Resident Medical Officer. Salary £71 per annum.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Election to the Court of Examiners.

ROYAL EAR HOSPITAL, 42 and 43, Dean-street, Soho, London.—House Surgeon. Salary £40 per annum.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—Clinical Assistants for six months.

RYDE, ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Radiographer. Salary £40 per annum.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Junior Resident Medical Officer for six months. Salary at rate of £70 per annum, with residence, board, and laundry.

ST. PANCRAS WORKHOUSE AND SOUTH INFIRMARY, Pancras-road, N.W.—Female Junior Assistant Medical Superintendent. Salary at rate of £100 per annum, with apartments, rations, and washing.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, lodging, and washing.

SCALEBOR PARK ASYLUM, Burley-in-Wharfedale.—Assistant Medical Officer. Salary £200 per annum, with board, apartments, attendance, &c.

SHEFFIELD ROYAL INFIRMARY.—House Surgeon for six months. Salary £80 per annum, with board and residence.

SMETHWICK, CORNWALL WORKS DISPENSARY.—Assistant Medical Officer.

STIRLING ROYAL INFIRMARY.—Resident House Surgeon. Salary £100 per annum, with board.

SURREY COUNTY COUNCIL EDUCATION COMMITTEE.—Three Assistant School Medical Officers. Salary £400 per annum each.

SWANSEA UNION WORKHOUSE.—Assistant Medical Officer. Salary about £260 per annum.

TAUNTON, SOMERSET AND BATH ASYLUM, Cotford.—Assistant Medical Officer, unmarried. Salary £200 per annum, with apartments, board, washing, attendance, &c.

UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.—Assistant in the Clinical Pathology Department. Salary £100 per annum, with luncheon.

UNIVERSITY OF LONDON.—Examiners.

UNIVERSITY OF LONDON, KING'S COLLEGE.—Demonstrator of Anatomy. Salary £100 per annum.

WALSALL AND DISTRICT HOSPITAL.—Assistant House Surgeon. Salary £90 per annum, with board, residence, and laundry.

WEST RIDING COUNTY COUNCIL.—School Oculist. Salary £300 per annum. Also Three School Dentists. Salary £250 per annum. Also Three School Medical Inspectors. Salary £300 per annum.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £100 per annum, with rations, apartments, and washing.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Acts at Clackmannan, in the county of Clackmannan.

Births, Marriages, and Deaths.

BIRTHS.

VERNON.—On Nov. 6th, at Wordsworth Lodge, Shirley, Southampton to Dr. and Mrs. Rupert Vernon, a daughter.

MARRIAGES.

DICK—WALLACE.—On Nov. 8th, at Highgate Presbyterian Church, James Reid Dick, M.B., B.C. Cantab., to Davina Orford, daughter of William Wallace, of Highgate, N.

SYMNS—SOWTER.—On Nov. 6th, at All Saints', Notting Hill, James Llewellyn Montfort Symns, B.A., M.B., B.C. Cantab., to Claire Hickling Dart Sowter, eldest daughter of John Sowter, of Derby.

THOMAS—PATERSON.—On Nov. 1st, at Upwey, Dorset, Robert Evans Thomas, M.D., to Mary, youngest daughter of the late William Paterson, of Dorchester, and of Mrs. Paterson, of Upwey, Dorset.

DEATHS.

CLENDINNEN.—On Nov. 6th, at Park-lane, Frederick J. Clendinnen, M.D., of Melbourne, Australia.

ROBINSON.—On Oct. 8th, suddenly, at Colombo, Morris de Lancey Robinson, M.D., B.S., D.P.H., aged 32 years.

SWEETING.—On Nov. 10th, at Fernshaw Mansions, S.W., Richard Deane Sweeting, M.D., Barrister-at-Law, Senior Medical Inspector, H.M. Local Government Board, Whitehall. Funeral private. No flowers, by special request.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SO-CALLED RITUAL MURDER.

To the Editor of THE LANCET.

SIR,—Mendel Beiliss, the Jew, has been acquitted at Kieff of the murder of the Christian boy, Yushinsky. This verdict therefore confirms the verdicts of previous generations in modern times. With reference to my letter in THE LANCET of Nov. 8th, quoting John Timbs, a further reference to the case at Damascus will be found in "The Historic Note-Book," by the Rev. E. Cobham Brewer, LL.D., published by Smith, Elder, and Co. in 1891. It runs as follows:—

> Jews of Damascus (Persecution of the), 1840. A Catholic priest named Thomaso of Damascus, having disappeared suddenly in February, a Jew barber at whose house he was seen was examined by torture, when he accused seven of the most wealthy Jewish merchants of being concerned in the murder. The seven merchants were apprehended; two died under torture, the other five pleaded guilty. A dreadful persecution of the Jews followed, and the absurd notion was confirmed that human blood was necessary for the paschal feast. The English and French interfered, represented to Mehemet Ali the absurdity of the notion, and the persecution ceased.

References to this matter are not easy to find, and the above is the only one which relates to it so far as my search goes. It is possible that the superstition arose from, or was inflamed by, the misinterpretation of symbolic pictures by the ignorant populace. In an old Jewish book discovered by a fourteenth century alchemist there was a picture of a king standing by while his soldiers killed the children of weeping mothers, together with allegorical pictures of the sun and moon bathing in their blood in a bowl. Reference will be found in "Popular Delusions," by Chas. Mackay, LL.D., published in 1856.

I am, Sir, yours faithfully,

Nov. 11th, 1913. A GENTILE.

NYASALAND HEALTH REPORT.

A REPORT on the Blue-book of the Nyasaland Protectorate (which comprises the eastern portion of British Central Africa) for the year 1912-13 has been issued by the Colonial Office as a Parliamentary paper. The European population, it states, is now 758, as against 773 in 1911-12. The native population is estimated at 1,020,537. The Asiatic population amounts to 356, as compared with 463 in the previous year, the decrease being accounted for by the disbandment of the Indian contingent of the 1st Battalion King's African Rifles and the consequent return of the troops to India. Twenty-seven European births were registered, as against 24 in the preceding year. The number of deaths of Europeans and Asiatics registered during the year amounted to 11 and 7 respectively, as compared with 7 and 8 in the preceding year. The European birth-rate was 35·62 and the death-rate 14·51 per 1000. Seven European marriages were celebrated. The health of the native population has been on the whole satisfactory, and there was complete immunity from serious epidemics during the year. The Royal Society's Commission has continued its investigations at Kasu in the vicinity of the sleeping sickness area. Up to the end of March, 1913, 126 cases of sleeping sickness have been recorded in the Protectorate, and during the year under review 63 cases were diagnosed, as compared with 25 in the previous year and 30 in the year preceding. Of the 63 cases diagnosed during the past year, 40 were males and 23 females. The increase in 1912-13, as compared with 1909-10 and 1910-11, is noteworthy; it would, however, be premature to draw deductions therefrom at this date, especially when it is remembered that, as the natives become accustomed to the presence of medical officers and have now no fear of cases being deported to a segregation camp, there is less likelihood of concealment of the sick as time goes on, and therefore the chances of finding a larger proportion of the infected will be correspondingly increased. The immunity of the native population from small-pox has been a satisfactory feature of the public health during the year, and though outbreaks of a sporadic character have been reported they have been due solely to infection having been conveyed from adjoining territories, and the disease in every instance has been rapidly checked. This satisfactory state of affairs is the result of the widespread and thorough vaccination which has been carried out during recent years and which is being continued throughout the Protectorate. The widespread existence of ankylostomiasis in the North Nyasa district formed the subject of investigation during the year, and it is intended to apply the District Administration (Native) Ordinance to this district with the special object of enabling Government to introduce a system of deep-trench latrines throughout the native villages. It is hoped that by this means the percentage of infected natives will be reduced and the physical condition of the natives improved. The danger to be

apprehended from the employment of Nyasaland natives as labourers in the South Africa mines and their return to the Protectorate with tuberculous infection is evidenced by the results of the medical examination of 1274 natives repatriated from the Transvaal mines during the year. It was found that no less than 3 per cent. were actually phthisical, while 9·5 per cent. were returned as suspicious cases.

SULPHUR AND TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 18th there is an annotation on the supposed preventive action of sulphur fumes on the development of tuberculosis. The week after this article appeared an old lady came to one of my branch dispensaries with a patient whom she had been treating by the novel method of rubbing flowers of sulphur into the back daily. She proudly pointed out that the patient had gained three pounds in weight during the first fortnight of treatment. This unqualified practitioner also informed me that she had "cured" many cases of cancer and consumption by this method, combined in the latter disease with the "breathing in" of sulphur fumes. Her only egret was that patients would not always submit to the inhalation reatment—the majority preferring the disease to the remedy.

I may add that I have not yet seen any of the cases "cured by this nteresting survival of the methods of Galenic medicine.

I am, Sir, yours faithfully,

R. C. HUTCHINSON,
Tuberculosis Officer for Carmarthenshire and Cardiganshire Area.

Carmarthen, Nov. 6th, 1913.

WOMEN AND SOCIAL HYGIENE.

THE *Gentlewoman* in its issue of Nov. 1st urges upon its readers the desirability of their entering on a crusade to instruct the people on the preciousness of human life, and to teach the simple hygienic rules whereby immense loss and suffering can be obviated. This, it points out, can be done without poking into little homes and upsetting mothers. It would have them begin with the educational authorities, not troubling themselves about the curriculum of a school, which can safely be left to the head masters and mistresses, but insisting that the school shall be run on hygienic principles, by urging the use of tooth-brush drill, the separation of tuberculous from non-tuberculous children, and the adjustment of the hours of study to the health of the child.

THE INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS.

AN interesting programme has been arranged for the Twelfth Session of the Incorporated Association of Hospital Officers which has for its objects the social intercourse of hospital officials, the study of hospital construction, equipment, and management, and other matters affecting the duties and responsibilities of hospital officers. Monthly meetings are held at the association's headquarters, 62, Chandos-street, Covent Garden. A conference has been arranged for March next between the association and the Poor-Law Officers' Association, and the Saturday afternoon visits include the most recently erected hospitals, concluding in June next with a visit to Birmingham and its hospitals.

PHARMACEUTICAL STUDENTS AND COMPULSORY LATIN.

THE council of the Pharmaceutical Society has amended in several respects the regulations concerning the registration of pharmaceutical students, the most important of the alterations being the deletion of Latin from the list of the compulsory subjects of the entrance examination. This decision is a sign of the times, and when one recalls that only 60 years have gone by since the London Pharmacopœia was issued in Latin it is a sign that we are moving rapidly. The decadence of Latin as the language of pharmaceutics began in 1864, when the British Pharmacopœia was officially published in English, and has lately been hastened by the educational policy of the schools from which chemists' apprentices are mostly drawn. Latin is not taught in these schools as an ordinary subject, and the result is that many a boy well suited to begin to learn pharmacy has chosen some other business for the simple reason that he could not pass an examination in Latin. The dropping of Latin from the compulsory part of the syllabus of the preliminary examination is, in fact, a corollary of the neglect of that subject by the secondary schools, and if blame is due to anyone for the council's decision it is to the schoolmasters. It is essential that there should be a steady flow of pharmaceutical students, preferably with a knowledge of Latin, but the flow must be maintained, and if Latin is clogging the stream it must go. In nearly all other countries the same tendency is observable; in Germany the Pharmacopœia is published in German, in France in French, in Italy in Italian, in Spain in Spanish, in Russia in Russian, in Sweden in Swedish. In Japan the last Latin edition of the Pharmacopœia was published in 1891, the present edition being in Japanese with an English translation. The new Norwegian Pharmacopœia is in the native tongue, and although the Pharmacopœia of Holland is issued simultaneously in Latin and Dutch, and the Belgian Pharmacopœia in Latin and French, few thumb marks would probably be found on the Latin pages of those in use. The same tendency is to be observed in the practice of prescribers, although the Latin prescription seems to die harder in this country than elsewhere. Notwithstanding, however, that Latin is no longer a compulsory subject for pharmaceutical students, they would be well advised to act upon the recommendation of the Pharmaceutical Society's council and take Latin as an optional subject. For candidates for the qualifying examination will still be required to pass a test in prescription reading which necessitates a knowledge of Latin, or at least a bowing acquaintance with it.

THE CASE OF MR. H. T. HAMILTON.

To the Editor of THE LANCET.

SIR,—To the donations already acknowledged (i.e., £54 5*s*.) I have now to add the following: Dr. Vaughan-Pendred, East Sheen, 10*s*. 6*d*.; Dr. E. B. Denny, East Barkwith, Lincs., £3 3*s*.; and Dr. Deane, Lincoln, £3 3*s*. I am, Sir, yours faithfully,

W. H. GIMBLETT, M.D.

86, Sutherland-avenue, Maida Vale, W., Nov. 11th, 1913.

THE MAGAZINE OF THE ROYAL FREE HOSPITAL (SCHOOL OF MEDICINE FOR WOMEN).

THE annual meeting of subscribers to this magazine will be held at the Medical School, 8, Hunter-street, W.C., on Thursday, Dec. 11th, at 4.30 P.M. All subscribers are cordially invited to be present.

COPYING PENCILS.

Messrs. Hardtmuth, Limited, of Koh-i-noor House, Kingsway, London, W.C., have sent us some of their "Mephisto" copying pencils, which they suggest will be found of service for duplicating reports under the National Health Insurance Act, and for any other purposes where indelible writing is required. From our own trial of the pencils, which are quite inexpensive, we agree with the professed claim.

A NEW MAP OF LONDON AND ENVIRONS.

A PRACTICAL working map of London, which includes on one sheet as wide a stretch of territory as from Harrow, Heston, Twickenham, Teddington, and Hampton on the west, to Chadwell Heath, Erith, Bexley, and Chislehurst on the east, and from Tottenham and Walthamstow on the north, to Kingston, Merton, Croydon, and Bromley on the south, is Stanford's "New Two Inch Map of London and its Environs" (price 5*s*. 6*d*.). A scale of 2 inches to the mile, in the hands of such skilful map-makers as Stanford's, gives scope for very considerable detail, and the names of streets are legible. The size of the map is 42 by 25½ inches, and it is printed on a tough paper that apparently will stand a good deal of wear and tear.

A.B.C.—As to the prospects of British medical graduates for practice in British Columbia, it should be borne in mind that there is a fairly good supply of young Canadian graduates. Moreover, though their *average* literary and professional standard may be a trifle below the *average* in this country, it must not be forgotten they are as a rule better equipped for the business side of practice. This is due partly to the fact that the average age for qualification is a little older, many of them supporting themselves by various business employments and earning the money for their medical curriculum.

G.M.S.—The reference to a previous issue which appeared in the paragraph on "Vaccination in the West of England" in our last issue was to THE LANCET of Oct. 25th, 1913, p. 1217.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced.

In 1913:—

Nov. 7th–15th (London, Olympia).—Twelfth International Motor Exhibition.

Dec. 16th–20th (Aberdeen).—Red Cross and National Health Service Exhibition.

In 1914:—

April 14th–18th (New York).—Fourth Congress of the International Surgical Society.

May 1st–Nov. 1st (Lyons).—International Town Life Exhibition.

July 6th–11th (Blackpool).—Twenty-ninth Congress of the Royal Sanitary Institute.

,, 8th–13th (Edinburgh).—Congress of the Royal Institute of Public Health.

Aug. 3rd–8th (London).—Sixth International Dental Congress.

,, 10th–15th (St. Petersburg).—Twelfth International Congress of Ophthalmology.

Sept. 7th–12th (Berne).—International Congress for Neurology, Psychiatry, and Psychology.

September (Vienna).—Third International Congress for Diseases of Occupation.

(London).—Anglo-American Exhibition.

(Aberdeen).—Eighty-second Annual Meeting of the British Medical Association.

(Auckland, N.Z.).—Australasian Medical Congress.

(St. Petersburg).—Third Mendeléeff Congress of Pure and Applied Chemistry and Physics.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Dr. D. H. Scott, foreign secretary to the Royal Society: On Medullosa Pusilla.—Prof. A. F. S. Kent: Neuro-muscular Structures in the Heart (communicated by Prof. C. S. Sherrington).—Mr. G. Graham and Mr. E. P. Poulton: The Alleged Excretion of Creatine in Carbohydrate Starvation (communicated by Dr. F. G. Hopkins).—Mr. J. A. Gardner and Mr. P. E. Lander: The Origin and Destiny of Cholesterol in the Animal Organism. Part XI., The Cholesterol Content of Growing Chickens under Different Diets (communicated by Dr. A. D. Waller).—Mr. W. E. Bullock and Mr. W. Gramer: Contributions to the Biochemistry of Growth—On the Lipoids of Transplantable Tumours of the Mouse and the Rat (communicated by Sir J. R. Bradford, secretary to the Royal Society).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF THERAPEUTICS AND PHARMACOLOGY (Hon. Secretaries: W. Langdon Brown, Philip Hamill): at 4.30 P.M.

Papers:

Dr. F. Ransom: Diabetic Gangrene and Encretion of Calcium.

Dr. R. W. Leftwich: On Uniformity of Dosage.

GENERAL MEETING OF FELLOWS at 5 P.M.

Ballot for Candidates for Fellowship.

SECTION OF PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart, C. Price-Jones): at 8.30 P.M.

Dr. R. A. Chisolm:

Dr. Warren Crowe: The Primary Cause of Rheumatoid Arthritis.

Dr. E. P. Minett: The Pathogenicity of an Organism Isolated from Non-ulcerating Cancerous Growths (communicated by Dr. J. W. H. Eyre).

WEDNESDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawfurd, D'Arcy Power): at 5 P.M.

Dr. Charles Singer: St. Hildegarde.

Dr. John Rolleston: Medical Aspects of the Greek Anthology (Part I.).

Dr. Raymond Crawfurd will show a collection of "Touch Pieces."

FRIDAY.—10 A.M., Gynæcological Lecture: Vulvar and Vaginal Tumours (continued). 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An Address
ON
THE ORIGIN AND GROWTH OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Delivered on the Occasion of the Opening of the American College of Surgeons,

BY SIR RICKMAN J. GODLEE, BART., M.S. LOND., P.R.C.S. ENG., &c.,
SURGEON-IN-ORDINARY TO H.M. THE KING; SURGEON, UNIVERSITY COLLEGE HOSPITAL, ETC.

GENTLEMEN,—At the beginning of the fourteenth century your ancestors and mine were living side by side—probably many of us have common ancestors—in those small islands from which I come. From which I come in response to your call, on a mission so honourable and responsible that, much as I appreciate the honour done to my College and to myself as its representative, I almost sink under the burden of its responsibility. I refer to this date because it has been suggested that some account of the origin and growth of the Royal College of Surgeons of England might be interesting to this assembly. Our attention is therefore for the moment fixed upon London and upon the earliest records of any attempt to regularise the practice of surgery in that already ancient capital of the British Empire.

THE GILDS OF BARBERS AND OF SURGEONS.

It is difficult for any of us, and most of all for you who have discarded almost all pomps and ceremonies, to visualise old England, primitive but stately, in 1308, the year after that weak King Edward II. had succeeded his politic and warlike father. It was near the end of the Middle, or the Dark, Ages. The new Parliament of Lords and Commons had hardly begun to make its influence felt upon the feudal system. The echo of the Crusades had scarcely died away in Europe, and England was constantly at war with France or Scotland. Everyone of any consequence bore arms, suits of mail and swords and bows. In fact, the military spirit pervaded everything, including the Church, and art and science were under a dark cloud.

Medicine was not in advance of the other sciences. Its practitioners were for the most part monks, or, if not ecclesiastics, cloaked their ignorance by the gravity of their semi-clerical attire.

In these early days surgery was regarded as a mere handicraft—much less dignified than medicine. For long surgeons were associated in the popular mind with the barbers, and even 200 years later we find them placed in the same list as "comon bakers, bruers or scrivenors." The barbers let blood and did other minor surgical operations, and those surgeons who belonged to the Barbers' Gild were not above scraping a chin or clipping a poll in their spare moments. Both trades were largely recruited from the continent, and both, no doubt, contained many undesirable aliens. Thus it was that Richard le Barbour, living opposite the church of All Hallows the Less, was elected and presented by the barbers of London, on Tuesday the Feast of St. Lucy the Virgin (Dec. 13th, New Style), 1308, to Nicholas de Faryngdon, then Mayor of London, and was appointed Supervisor of the Gild, and swore the Barbers' oath, from the words of which it may be gathered that there were some very black sheep indeed in the profession in those days. This is the first mention in the City Records of the Barbers' Gild.

The better class of surgeons, known as the master surgeons, apparently held aloof and formed themselves into another association called the Gild of Surgeons. When this Gild of Surgeons was founded it is impossible to say, but we know that by 1368 surgeons were recognised as a distinct body, and in 1492 they were granted arms (the original of which is still preserved in Barbers' Hall). I prefer the words of their license to those of the Barbers' oath. They promised "well and truly to serve the people in their cures, to take of them reasonable fees, to exercise their mystery [which means *mestier* or trade] faithfully, to report to the Mayor and Aldermen any surgeon neglecting his patients, and to give information to the city officers of the hurt, wounded, or otherwise in peril of death."

The Origin and Development of Gilds.

It is interesting to think of the origin of these Gilds, although it is one of those doubtful questions which are the delight of speculative historians. Perhaps it is to be sought in the purely pagan and Scandinavian idea of wergeld, or the price of blood, or possibly it is founded on the Christian idea of brotherhood. Be that as it may, we find in England soon after the Norman Conquest, over and above religious gilds with which we have nothing to do, both in the large and small boroughs what was known as the "gild merchant," an association distinct from the municipality for the protection of trade in general. From the gild merchant, as it were by a process of fission (like that which perhaps unfortunately is taking place so frequently in our own profession to-day), were separated the gilds of particular crafts. As these grew more powerful and more numerous the parent body became superfluous and obsolete and gradually disappeared. The gilds then were associations or fraternities of all the artisans of a single branch of industry in a particular town for mutual protection and support, for the supervision of the craft and regulating the hours of labour. They always retained something of the religious element. Charity and almsgiving in sickness and old age were never forgotten, and brotherly feasts or banquets appear to have been the *sine quâ non*.

In London these gilds in the course of time gave place to the City Companies. They became very important bodies, they elected and still elect the Lord Mayor and Corporation, and had judicial functions independent of the Crown.

In the time of Edward III. everyone belonging to a craft was obliged to join a company; and surgery being recognised as a craft it was essential that surgeons should either join the gild or company to which they were most closely associated—namely, the Barbers—or should form one of their own. As a matter of fact, as we have seen, both these courses were adopted.

The master surgeons, forming the Surgeons' Gild, who no doubt represented the *élite* of the profession, gradually gained strength and influence, and it is not surprising that considerable friction occurred between them and the barbers practising their minor surgery. It may be noted in passing that in those early days the master surgeons recognised the practice of women, and held some of their writings in high esteem, notably those emanating from the University of Salerno.

There is no time, and it would be tedious, to dwell upon the various steps by which the barbers became a City Company, acquired a coat of arms, and lived sometimes at peace but oftener at variance with the Gild of Surgeons. For the present also a passing reference only is made to the promising but unfortunately short-lived associated College of Medicine and Surgery and the establishment of the College of Physicians in 1518, on the model of the Paris College. To this and the disagreement between the two branches of our profession I will return later.

THE COMPANY OF BARBER-SURGEONS.

But now, leaving all this very ancient history, I will direct your attention to a period 200 years after the time of Richard le Barbour, when in 1542 or thereabouts the Barbers' Company and the Gild of Surgeons were incorporated as the Company of Barber-Surgeons.

These two centuries had been marked by universal and extraordinary progress. The dark ages had given place to the Renaissance or the revival of learning. Printing had been invented, rendering knowledge common property; gunpowder had been discovered; and the most important branch of the surgery of those days had thus been profoundly modified, while the general outlook of the world had been changed by the voyage of Columbus to your continent across the Atlantic. There were still frequent wars and rumours of wars. England itself had hardly settled down after the Wars of the Roses, but the military spirit was less preponderant. Our mutual forefathers were with much travail shaking off the tyranny of Rome, and the real spirit of the age was inspired by the cultivation of art, science, and the *literæ humaniores*.

Our own science had been revolutionised by Ambroise Paré, Paracelsus (that erratic genius), and others, and it is not to be wondered at that surgeons were becoming more important and perhaps more aggressive.

There was a tendency, from the point of view of concentrating force and avoiding friction, for the different City Companies to amalgamate. New economic conditions caused the pendulum to swing back, and diffusion again was giving place to concentration. It was to promote peace and secure uniformity that the new Company of Barber-Surgeons was formed, the outward and visible record of which is Holbein's notable picture in Barbers' Hall. To stand before it is to grasp the spirit of the age. Henry VIII. in gorgeous robes of State gazes loftily into space, as if with a soul above such trifles, holding a drawn sword in the right hand, while with the left he casually presents the charter to the kneeling barbers and surgeons, appropriately clad in their black caps and flowing fur-tipped robes. Amongst them is to be seen Thomas Vicary, the first Master. This was the gentle-minded Thomas Vicary, sergeant-chyrurgeon to the King and overseer of all the officers at St. Bartholomew's Hospital. He was the author of "The Englishman's Treasure with the True Anatomie of Man's Body," in which, amongst other noble thoughts, he gives this sound advice to surgeons:—

> And see they neuer prayse themselves for that redoundeth more to their shame and discredite than to their fame and worship: For a cunning and skilful Chirurgeon neede neuer vaunt of his dooings, for his works wyll euer get credite ynough. Likewise that they despise no other Chirurgeon without a great cause: for it is meete that one Chirurgeon should love another, as Christ loueth vs al. And in thus dooing they shal increase both in vertue and cunning to the honour of God, and worldly fame, to whome he bring vs al. Amen.

THE SURGEONS' COMPANY.

The unnatural union of Barbers and Surgeons lasted for another 200 years, but it was never a success. The contracting parties were incompatible, and the incompatibility increased as surgery began to emancipate itself from the superstitions and traditions of the elders under the influence of advancing scientific thought and discovery. During these two centuries much had taken place on both sides of the Atlantic. Spanish, Portuguese, Germans, Dutch, French, and English had migrated in large numbers to North America; and the English colonies were exerting more and more pressure on their Spanish and French neighbours. In England the Stuarts and the Commonwealth had come and gone, and the House of Hanover was firmly established on the throne when in 1745, after 60 years of agitation, the Surgeons' Company was separated from the Barber-Surgeons by Act of Parliament.

In obtaining their release the Surgeons were only following the example of Paris, Edinburgh, and Glasgow; but the Barbers naturally resented this divorce from their more distinguished and more prosperous partners. So they drew up a reasoned protest in which they finally urge:—

> But if for other reasons (which the Surgeons say *may* be given) the Parliament shall be inclined to favour them in this part of their Report the Barbers, from the scrupulous Regard and Tenderness which that august assembly has always shown for *private Property*, cannot but hope that they shall be *continued* in the enjoyment of all their Possessions without any diversion whatsoever.

And so it was settled. The Barbers kept everything—hall, plate, and pictures, and the Surgeons had to make a fresh start on their own account. Cheseldon, who, in his scarlet coat, watches over our Council meetings, was a prime mover in the change, and Mr. Ranby, sergeant surgeon to George II., was the first Master.

THE FUNCTIONS OF THE COMPANY OF BARBER-SURGEONS.

In order to grasp the evolution of our College we must glance at the functions—*quoad* surgery—of the Barber-Surgeons during this second period in our historical review. The orthodox training for a surgeon was by means of apprenticeship, and the Company supervised the quality and training of the apprentices and examined them before granting the licences, which then had to be approved by the Bishop of London or the Dean of St. Paul's. At times they had trouble with these worthies, who were apt to give licences on their own account without proper examination. The Company also gave licences, sometimes partial, sometimes temporary, to foreigners, and it is to be feared sometimes to the merest quacks. They also did not hesitate to take them away again if occasion arose.

The licensing of naval surgeons was also committed to them. One of their important functions was the public dissection and teaching of anatomy, the only form of anatomical study recognised by law. For this purpose the bodies of four executed criminals were allowed each year. Another was the appointment of public lecturers or readers on surgery. But this was apparently not a very successful venture. Besides this they exercised a censorship over the books of their members, and had the power of summary commital for minor offences.

But the fact of belonging to an important City Company hampered the surgeons greatly. They had to take part in City functions and public pageants, and were heavily assessed for public objects, such as the repair of St. Paul's Cathedral, or Irish necessities. Countless dinners exhausted their coffers, and it is not to be wondered at that their valuable plate was frequently at pawn, and that at one time the Company actually became bankrupt. One cause of their difficulties was the rise and increasing prosperity of the medical schools with their more attractive, shorter, and less expensive system of training or apprenticeship—less expensive because no part of the hospital fees was wasted in defraying the cost of civic extravagance.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

And now, since the separation of the Surgeons from the Barbers and the formation of the Surgeons' Company, another 200 years has almost passed away, and our College stands before the world *totus atque rotundus*, for criticism or praise. Let us shortly glance at the intervening period.

The new Company passed through many vicissitudes, monetary and domestic, both in their original quarters in the Old Bailey and also in our present house in Lincoln's Inn-fields. In 1800 they were established as the Royal College of Surgeons in London by a charter of George III., and in 1843 the name was changed, by a charter of Queen Victoria, to the Royal College of Surgeons of England. In the meantime the ancient titles of Master, Governors, and Court of Assistants had been replaced by those of President, Vice-Presidents, and Council.

I will not burden you with a detailed account of the gradual development of our constitution, nor of the steps by which the corporation was enlarged to its present size. But it will interest you to hear that under the 1843 Charter a *new Class of Members, who were to be called Fellows*, was formed, from and by whom the Council were to be elected, instead of, as was previously the case, by the Council themselves. The idea was to enlarge the franchise without making it unwieldy, and in practice I think it works well. But there are murmurs from a small but active section of the Members, whose shibboleth is the phrase, "the modern idea of representative government." Students who passed the necessary examinations obtained their *quid pro quo*—the diploma of Member—which carried the right to practise and certain privileges, exemptions, and immunities. They also became by law an actual part of the body corporate. If this had not been the case, and if they had been called Licentiates, as is the case at the College of Physicians or the Apothecaries' Hall, they would have had no suspicion of a claim to the franchise. And if our College were still struggling and impecunious it is possible that the high philosophical, democratic idea would not have suggested itself. Now the Members number over 17,000, most of them busy general practitioners; they are scattered over the three kingdoms and the colonies, and many are in the services. They would form an unpollable constituency, and it may reasonably be feared that if universal suffrage were adopted only the comparatively few advocates of the change would be represented, and that an attempt would be made to import an expensive socio-political element (now well looked after by other bodies) into what is undoubtedly the proper function of the College.

The Fellowship of the College.

The first Fellows, 300 in number, were chosen from the Members. They were elected by the Council, chiefly from the surgeons, assistant surgeons, and lecturers of the metropolitan hospitals. A second batch of 242, elected in 1844, included many representatives of the Naval, Military, and Indian Forces. Since then the ordinary portal to the Fellowship has been an examination, or rather two examinations, which together constitute a formidable and searching test of ability. Our critics say that the number of rejections at them is out of all reason, and I am not prepared to say that the criticism is unworthy of consideration. At the same time it must be remembered that the Fellowship is not a mere qualification to practise, but is intended to mark its holders as having undergone a thorough training and examination in anatomy, physiology, pathology, and surgery, and also that in spite of all its difficulties there is no lack of candidates for what is the most coveted British surgical distinction. The number of Fellows is now 1589.

An elected Fellowship is to form the first Corpus of your College, but you will be faced with the problem of its renewal and enlargement if it is to be an active, moving force. I will therefore briefly describe our method of attaining this result, because it appears preferable to that which is adopted by the Royal Society and the Royal College of Physicians of London—namely, to elect a certain number of Fellows every year. Ours, at all events, excites no jealousy and causes no heartburning. I know it has been suggested that the presentation of a thesis might replace or supplement an examination. But it must be remembered that many excellent practical surgeons might find this an arduous, if not an impossible, task; and also that the professional thesis writer is not unknown where this practice prevails.

The Examinations for the Fellowship.

For the First Professional Examination four examiners in anatomy and four in physiology are selected from the professors in these subjects at universities and medical schools. The papers of each candidate are read and marked by two examiners in anatomy and two in surgery. Each candidate is then subjected to a searching oral and practical examination by the other two examiners acting together. No candidate is examined by his own teacher, and successful candidates must obtain a high percentage of the total marks. For the Second Professional Examination the ten examiners are surgeons on the staffs of large hospitals connected with medical schools. It consists of a written paper, an elaborate clinical examination, both written and oral, operative surgery on the cadaver, surgical anatomy and surgical pathology. In each part the candidate is examined by two different examiners, one questioning and the other assessing. Thus, before the ordeal is complete, he has appeared before all ten examiners, and on their joint award he is either passed or rejected.

If you contemplate anything of the sort and desire that the diploma shall indicate, not only that a man can pass a severe examination, but that he has been thoroughly well trained, you will be well advised to lay down a special curriculum (I speak the word with dread) over and above that required in the ordinary university course, and to frame the examinations on a standard even higher than the highest degree examinations. It is, in my opinion, essential that the examination should be

conducted independently of any medical school, and that the examiners should be chosen only from those who are actually engaged in teaching. It is also highly advisable that examiners should, whenever it is possible, be Fellows of your College and that no candidate should be examined by his own teacher.

Before leaving the subject of the Fellowship it is proper to state that our Council have the right to appoint *ad eundem* Fellows, but there is only one of these. They can also elect to the Fellowship annually two Members of 20 years' standing, but this privilege also is sparingly used. By a charter of 1908 (which was the centenary of the College) a new order of Honorary Fellows, limited to 50 in number, was instituted. This includes a few personages of distinction who do not belong to our profession, as well as representatives of the flower of surgery in all parts of the world, some of whom I am proud to think form part of my audience.

The College: Museum and Library.

I must now pass to the consideration of what we are and what we do to-day, though the thought obtrudes itself, What use can these musty old traditions and tedious evolutions be to you who are in the act of springing fully armed like Minerva from the head of Jove? It requires an effort to appreciate the youth of this enormous city. When Lister was planning his visit to the United States in 1884 he turned up his ordinary everyday atlas to study the route and looked first for Chicago, but lo, it was not to be found! Will you bear a little longer with the prattle of one who, compared with yourselves, is like a pliocene pithecanthropos?

We are now, as things go, in comfortable circumstances. Our affairs are well managed and we can put by against the day of adversity—a very necessary precaution in these times of political instability and social unrest. The College, a large and dignified building, standing on freehold property, contains amongst other things a theatre, laboratories, a library, and the museum.

The nucleus of the museum is the famous collection of that genius who may almost be called our patron saint, John Hunter. It was bought by the nation, and though it was handed over to our custody it is actually in the hands of trustees. It is thus a national institution, but the greater part of it is our own, for we have spent since 1800 no less than £500,000 upon it. It is now probably the best of its kind in the world, and is resorted to largely for study and research. The development and improvement of the museum is one of our primary duties.

The library contains 60,000 volumes and perhaps an equal number of pamphlets. This of course is small as compared with those of the Faculté de Médecine at Paris, or the Militär-Medizinische Akademie at St. Petersburg, or your own magnificent Surgeon-General's Library at Washington. It is, however, if not the best, one of the two best medical libraries in London, and is very largely used.

The Council: Disciplinary Functions.

The affairs of the College are managed by a Council of 24, who cannot sit for more than eight years without re-election and seldom serve for more than two terms. The Council meets once a month. Most of the work is done by committees; it is concerned with public as well as our own private affairs. The Council have also certain disciplinary functions and supervise the examinations for our own special diplomas (the Fellowship, the Diploma of Public Health, and the Dental Diploma), as well as those granted in common with the College of Physicians.

In speaking of the disciplinary functions it must be remembered that our General Medical Council has definite judicial powers over registered medical practitioners entrusted to it by Parliament. It can institute inquiries, take evidence, and deliver judgment. It can erase the names from the Register of those found "guilty of conduct infamous in a professional respect." Our College has only jurisdiction over its own Fellows or Members, and is not in the same sense a judicial body, but it often investigates complaints and, accepting the decisions of the courts of law or the General Council, deprives members of their diplomas, sometimes restores them, or issues reprimands for minor offences, and thus endeavours to maintain the respectability and dignity of the profession. It is a very delicate subject and one which I am sure will give you very serious matter for thought. You will be fortunate if you escape the criticisms sometimes made upon our actions, either that we have proceeded with too great temerity or with excess of caution.

Possibly it is the hope of some active promoters of this scheme that a system of ethics may be set up and enforced acceptable to the whole North American continent. It is a Herculean task, not unworthy of a modern Hercules.

In studying our own history one is struck by the fact that the crime of one age may be either unthinkable or altogether condoned in the next. In old days punishment was inflicted on an unlicensed person for hanging out a flag to indicate that he was a surgeon, or on a surgeon for wilfully exposing his dirty bleeding cups in the shop front, or—observe—for prescribing an internal remedy. Touting for patients is an old offence, but the Insurance Act with us appears to be forcing the censors to judge it less harshly. And not only Time, but Place, exerts its influence on the code of medical ethics. What may be considered merely bad taste, or hardly that, in one country is disgraceful in another. Even the method of issuing an advertisement makes all the difference in the eyes of the moralist. So that sometimes as the black ball is reluctantly dropped into the box I seem to hear the words of the parable, "Let him that is without sin amongst you cast the first stone." When I think of your vast continent, of its polished eastern civilisation, of its wild west and its even wilder south, I feel sure that in the matter of discipline you will have to tread with cautious steps lest you should defeat your object; bearing in mind the words of Thomas Vicary quoted above, "likewise that they despise no other Chirurgeon without great cause."

EXAMINATIONS.

The subject of examinations is a dry one, but it is worthy of your serious consideration; and I trust that by omitting any further reference to the Fellowship and the special diplomas it may be possible to hold your attention.

Many of the time-honoured institutions in England are the result of slow growth, of patching together and preserving what is good in the old and by degrees eliminating the bad. The result is often passable but not perfect, and our system of medical examinations in the three kingdoms shares the fate of many arrangements of the kind. *Video meliora proboque* (I recognise and approve of something better) should be our motto, and I gather that your

position, at all events in the States, is not a much more happy one.

My own view is, but I commit no one else in expressing it, that the ideal plan would be that in every country the qualification to practise should be granted as the result of a uniform examination, controlled or authorised by the State, something much more practical and efficient than the German Staatsexamen. And by *State* I mean not one of your States, but *country*, for I do not think it possible that a single scheme should be adopted by a huge continent like this, with its Latin and Teutonic elements living side by side. Canada is showing the way, and I can imagine that the United States and Mexico—each surely large enough to form a unit (the United States is indeed probably far too large for the purpose)—might take a hint from the Dominion, where, as I understand, a General Medical Council has been formed which will in future control the examinations which alone will confer the right to practise. There are other ways in which the result might be obtained; but even if this were a suitable occasion I am not sufficiently acquainted with your special difficulties to pursue the matter further.

In any country where such a test is enforced the examinations for the Fellowship of Colleges and the degrees of Universities need no longer traverse the whole of the medical curriculum, as they would no longer carry the qualification. They need only include whatever special polish the particular body thought it advisable to apply to the individual who had already obtained the seal of his country upon his general fitness to practise his profession.

With us more or less uniformity of standard has been obtained by means of the powers entrusted by the Privy Council (from whom the right to hold qualifying examinations originates) to the General Medical Council, of inspecting and reporting upon the examinations of the far too numerous qualifying bodies. But it is impossible to overlook the dangers of underbidding and underselling, and the unnecessary and unprofitable toil imposed upon the student who may desire to possess, say, both a University degree and our Conjoint diploma.

The serious and prolonged attention that the American Medical Association have devoted to this subject, and the very fact that we are assembled here on an occasion that may almost be called a solemn one, for the inauguration of your College makes it certain that some changes will before long take place. It is my earnest hope that they may be wisely made. Of one thing I am profoundly impressed, that a uniform standard is essential for the best interests of the public and the profession, and that no such uniform standard is likely to be obtained unless the profession is unhampered in its endeavours by political or parochial interference.

Until about 25 years ago the examinations for the Membership of our College of Surgeons included rather trivial examinations in medicine and midwifery, and, like those for the Licence of the College of Physicians, carried a qualification to practise. But in 1884 a Conjoint Examining Board of the two Colleges was formed, on which each is represented and each discharges its own proper function. Successful candidates become Licentiates of the Royal College of Physicians and Members of the Royal College of Surgeons, and there is no other way of obtaining these diplomas. It is not too much to say that these examinations are recognised as being models of fairness and thoroughness and are specially distinguished by their practical character. There are those who hope that, if a State test is ever instituted in the old country, they will at least be taken as its pattern.

THE RELATIONS OF PHYSICIANS AND SURGEONS.

This *rapprochement* between the two Colleges is one of the most satisfactory developments of modern times, and is one to which I desire particularly to direct your attention. I am in complete agreement with a recent statement by one of your most thoughtful surgeons, that as surgery becomes more and more scientific and involves the treatment of all the internal organs it is natural that surgeons should be more than mere superficial physiologists and pathologists, that they should become, in fact, physicians as well as surgeons. My own practice has largely been upon the border-land, and I have all my life pointed out that, whereas the pure physician *need* not be conversant with the details of surgery, the more he knows about them the better; but that it is essential for the well-equipped surgeon to make himself acquainted with much of what is considered to be the special domain of the physician. Surgeons who specialise often become adepts in the medical aspects of their own specialities; and it may well happen (if they do not excite jealousy by *practising* as physicians that their opinions will be sought by their medical colleagues, not only in respect of treatment, but also to assist in diagnosis.

The tendency, therefore, ought to be for the two branches of the profession to be drawn more and more closely together, and it may confidently be anticipated that in forming an American College of Surgeons nothing will be done to widen the interval or accentuate the divergence between them.

In London the two Colleges are now on the most friendly terms, and in many matters act in common for the good of the profession and the community. But there is no chance that we shall ever amalgamate. Our traditions are so different; there is but little similarity in our constitutions and our methods of doing business. And seeing that what has been said about single as opposed to married life—"he travels the fastest who travels alone"—is true also of corporations, we shall no doubt each for the most part pursue our own course, completely emanicipated, however, from the petty rivalry and discord of former days.

It is strange to think that about 1420 a *College of Medicine and Surgery* was actually established within the liberties of the City of London—that is, you will observe, nearly a century before the foundation of the Royal College of Physicians. It is also a sad reflection that, powerful as it was and promising as its prospects appeared to be, the two parties in it could not succeed in working harmoniously. Later on the two Colleges were often at deadly feud, the principal complaint of the physicians being that the surgeons persisted in administering internal remedies. At one time they positively refused to meet one another in consultation. It is much to be deplored that the original scheme failed. It came too early in the world's history. But in this age of reason, if I were framing the constitution of a modern Utopia, I would found such an associated college, which, of course, would be an unqualified success, for even the schemes of the ancient Utopia, we know, were always not only theoretically unimpeachable, but practically perfect.

Concluding Remarks.

Utopia! The word reminds me that on receiving your invitation I thought it might be necessary to adumbrate the *perfect college* which yours I trust will be. But I will not attempt to do so. Your College, by the very nature of things, must be, both in structure and function, totally different from ours, and ignorance of the local conditions would lead me into hopeless difficulties. For example, you may intend it to be, like the Church Universal, an impalpable something enshrined in your minds and consciences, but I can hardly conceive of it without a stately habitation, over the door of which is the inscription, "*Aedes Collegii Chirurgicorum Americanorum.*" Only where? Naturally the first thought that occurs to an Englishman is Washington, but the vast extent of your continent at once suggests objections which might be raised. Again, my idea of a college includes a magnificent and expanding library, but it would be a waste of effort to duplicate your own national Surgeon-General's Library. If your temple ever rears its head, at least I hope that you will have a museum modelled upon, and perhaps some day surpassing, the Hunterian Museum in Lincoln's Inn.

These things are, however, merely the outward coverings and the skeleton of the college. You are the flesh and blood, the circulation, the primæ viæ, the nerves and the brains, and it is for you, and you alone, to work out your own salvation. No advice of mine beyond the hints scattered here and there very tentatively through this address can, I fear, be of any service to you; it is my fervent hope that what I *have* said may at least not appear injudicious or impertinent.

Let me therefore in conclusion return to the thought with which I began—namely, the happy inspiration that suggested to you to invite the College of Surgeons of England to send their President to mix the caudle cup for your christening. It was, I assure you, most willingly and heartily accepted by them. The brotherhood of science is an intimate relationship, but we are so widely scattered over the face of the globe that it is apt to be overlooked. Anything, therefore, is to be welcomed which helps to remind us that we are all brothers, in spite of diversity of tongues and dividing seas. But in the case of America and England such interchange of thought, such interchange of courtesy and hospitality, have a still deeper and a more important bearing. It is not simply because we are fellow labourers in the same *scientific* fields that we thus meet together—now on this side of the Atlantic, but soon, I hope, on the other—but because as *nations* we have long since beaten our swords into ploughshares, and are intent upon cultivating those fruitful acres of mutual forbearance and respect.

City of London Hospital for Diseases of the Chest.—The annual dinner of this charity will be held on Dec. 3rd at the Trocadéro Restaurant, London, when Sir Philip Sassoon, Bart., M.P., will take the chair. The hospital, which has 175 beds and over 10,000 out-patients annually, is the second largest hospital in London for consumption. It is situated in a healthy position but remote from wealthy residential parts, and but for substantial recognition by King Edward's Hospital Fund would have suffered severely from pecuniary pressure. The purpose for which the committee of the hospital are at the present moment seeking special assistance from the public is the improvement of the sanitary arrangements in the older portion of the hospital and the modernising of the heating system.

An Address
ON
SOME REQUIREMENTS FOR MODERN CLINICAL TEACHING.

Delivered before the Medical Institution of Liverpool on Nov. 6th, 1913,

By Sir DYCE DUCKWORTH, Bart., M.D., LL.D., F.R.C.P.,

HONORARY MEMBER OF THE INSTITUTION; CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND THE ITALIAN HOSPITAL; SENIOR PHYSICIAN TO THE SEAMEN'S HOSPITAL, GREENWICH.

Gentlemen,—My first duty is to thank the officers of this institution for this opportunity of addressing my professional brethren in this my native city, a place endeared to me by long and touching memories, not a few of which, indeed, relate to old members of this society, now passed away to their rest.

Medicine and Science.

I have selected the subject of clinical teaching because it has become one of supreme interest and importance, and concerns the highest welfare of all our British Schools of Medicine. It is certain that profound changes have occurred within recent years in our clinical methods which were not conceived as possible when many of us were students.

Let me make my standpoint in this matter clear from the outset. It is sometimes asserted that physicians of my standing are now little better than pre-scientific fossils, unfitted to realise or avail themselves of modern methods and research, for which they were never trained, and who therefore venture to believe that they may safely discard them. Thirty-eight years ago Burdon Sanderson expressed his profound conviction "that a future will come, it may be a somewhat distant future, in which the treatment of disease will be really guided by science." Two years later Claude Bernard remarked that "the old traditions are losing ground, and scientific medicine (*la science expérimentale*) has got hold of all our younger men." These were indeed prophetic statements from two great physiologists, and we shall do well to note what has happened in the interval, and ascertain if the practice of medicine has yet reached the high scientific position anticipated for it. We may roughly sum up the advances which have materially altered our methods as results of studies in bacteriology and biochemistry. Many of these have proved fruitful for the benefit of humanity, and we are justified in expecting fresh disclosures in the days to come. They are indeed so remarkable that no intelligent member of our profession can afford to be ignorant of many of these achievements wrested from nature. The laboratory has therefore become an important and essential adjunct to the clinical ward.

Being still engaged in clinical teaching, I venture to assert that while my position and training exclude me from taking any part in laboratory methods and research, I am yet enabled to summon from this source the best expert revelations for the benefit of my patients and my pupils, and I am constantly doing so. I recognise to the full the value and essential importance of all these modern methods, and gladly urge the experts to further advances. We surely know that legitimate medicine can never stand still and live on even the best of its past.

The task before us to-day is complex and indeed difficult for any clinical teacher. He dare not shut his eyes to the achievements of his great predecessors, and yet he must be ready to take advantage of the best modern assured facts and methods of inquiry.

Let it be noted that his great centre in this matter is the true welfare of his patient, for the physician is a healer by profession, and he must secure from all sources the best possible knowledge to enable him to make an exact diagnosis, to treat his patient, and to frame a sound prognosis as to the outcome of any ailment affecting him.

Medicine as an Art, guided by Scientific Research.

Modern medicine is now declared to be gradually becoming a branch of experimental science. I do not accept this pronouncement. I prefer to affirm that medicine is an art, guided increasingly by the disclosures of scientific researches, and I venture to declare that if clinical work was conducted at the present time solely from a scientific standpoint, without any reference to the personal factors of our patients, it would often fare badly for them.

The physiologist's standpoint is not that of the physician. The former is not a bedside artist, and has little knowledge of the inward human elements in the ailing human individual. He is often devoid of clinical instincts. His work is impersonal and confined to soulless materials. The physician ministers to mind and soul as well as to tissues and secretions, and he has to discern the subtle difference in the living, though sickly, organisms with which he has to deal. This faculty for observation of the personal factor in each case varies, of course, in different individuals. In some it almost amounts to an instinct, and in any instance can only be acquired by study at the bedside. The physician needs all the best knowledge that the physiologist and biochemical professor can give him, but he has to apply it with prudence in his own way as directed by experience. That is not science properly so-called, but it is a great and imperative requirement for success in practice. Doubtless many bedside problems are best resolved in a clinical laboratory closely adjacent to the patient, and we are now establishing those aids to diagnosis in all our best schools. We may note, however, that if such researches are not conducted by experts they may lead to wrong interpretation, and be unavailing or even harmful.

There are some amongst us who do not hesitate to regard a good deal of the clinical art of to-day as little better than an old-fashioned empiricism, and the modern scientific physician appears to have set himself to dispense with all matters which smack of it. It is supposed to be unnecessary and fruitful of errors. The modern surgeon, it is true, may generally find small place for anything empirical, for he has had little need for such practice, and his work is not seldom plainly set before him. Much more plainly, indeed, to-day owing to the admirable work which surgeons have done of late years in interpreting what Sir Berkeley Moynihan aptly terms "living pathology," especially in respect of the abdominal cavity. The physician readily appreciates most of the fruits of modern surgery, and is gravely in fault if he hesitates to secure promptly such aid as can be secured from the surgeon for his patients. It has to be conceded that surgery has now taken over into its department several chapters in medicine, and our surgical colleagues are ready to deal with every cavity in the body in which operative measures are possible or desirable.

I trust that, thus far, my hearers may give me credit for an open mind in regard to modern methods, and gather that I am unprejudiced and in no degree jealous, but truly very proud, of the splendid achievements of modern surgery.

WHAT EMPIRICISM REPRESENTS.

I have a good deal more, however, to say about the physician and his work, and I would ask you first to consider what empiricism in medicine represents to-day. Sir William Hamilton's definition of the term was: "Experiment or experience without science." I venture to think that such terms can hardly apply to much of the empiricism of this century, for it is certain that the phenomena of disease are now carefully studied by physicians already trained in scientific methods. The results of treatment are no less rigidly noted by them as a scientist would note them. A preferable, but still incomplete, definition of empiricism is: "The product of experience, founded on observation alone." In this case it cannot be an asset in the equipment of any young practitioner. Observation is the keynote of the physician's life work. He should start in practice as a well-trained observer. (I note a special defect in modern preliminary training owing to an inadequate teaching of the subjects of botany and materia medica, which are of much value in promoting observation of details.) Precision and accuracy in seeing and recording are of high value as acquirements. The imperfectly trained observer is often blind to matters that become almost instinctively borne in upon the well-trained one, and as Browning wrote: "Men won't notice; when they do they'll understand."

The Training of the Student.

The reformers of our medical curriculum contend that unless a student is scientifically trained to research and to watch for new results his education is defective. I believe that such training is now adequately secured for the average student in his present compulsory studies in the physiological and bacteriological laboratories of our best schools. Original research is hardly possible for him *in statu pupillari*, yet such work has always been carried on by aspiring students who, with exceptional industry and ambition, find time to do it. Modern teaching in all departments is now conducted by scientifically trained observers, and they surely impart the methods and fruits of such training in their daily duties.

I am inclined to believe that the scientists are now unduly pushing their subjects into the curriculum of our students, and thus withdrawing them from an adequate pursuit of their clinical duties. The modern curriculum is indeed heavily loaded already. The exceptional student must be blessed with more time and money than falls to the lot of the ordinary one, and let us remember that the instinct and taste for original work are not universally implanted in the minds of our pupils, who for the most part have to be prepared for the particular practical duties that await them.

We must face the facts with which we have to deal. We do not find the same types of mind in this country which we meet with in foreign countries. Our methods are, and always will be, different. We have to take the best we can secure from all sources, but we shall employ them in our own way as seems most profitable for the end in view. I

believe that we are now doing this in all our best schools, while we pursue methods of our own which it would be well for many foreign schools to adopt. We can at least illustrate for them the art of nursing the sick, surely a clinical matter, and display in our hospital service a ministry of humanity not too readily met with in foreign cities.

Rational Empiricism.

I therefore regard the term empirical, in its ordinary sense, as an improper one to apply to a skilled modern medical observer; and I prefer to regard a rational empiricism as a fine part of the *ars medendi*. I have a strong opinion that the best practice of medicine will never be completely covered by what we recognise as science, properly so called. Have we not discovered for ourselves that highly scientific practitioners are not always the best clinicians, nor are they the men to whom we should prefer to trust our lives, or those dear to us, in grave diseases? Such opinions cast no measure of indifference on scientific methods and attainments which must always be appreciated and encouraged.

Sir Oliver Lodge has lately reminded us that "the methods of science are not the only way of arriving at truth," as is now too commonly believed. The two methods, rational-empirical and scientific, are distinct, and equally imperative, and they must be blended as required in our practice. It cannot be denied that a large part of successful medical practice is rationally empirical, and cannot be explained in the terms of an exact science. We can neither afford to wait, nor our patients to suffer, until scientific principles govern all our therapeutic efforts, and we are prepared with exact explanations of their efficacy.

I suppose that the work done by such clinical masters as Bright, Trousseau, Graves, Addison, Jenner, and Murchison, not to mention many others, is now regarded by some of us as of secondary importance and little adapted for modern teaching. Apart from their enduring contributions to pathology and treatment, we must recognise that much of their practice was guided by a rational empiricism which they exerted with skill and trained experience. I maintain that we must still work on similar lines to-day, better equipped indeed than these men were, and seeking our knowledge largely from close and accurate bedside observation. We may remember that these men thought and worked in days of less pressure and strife than those we are living in. There was then more time for meditation and fruitful thinking, less eagerness to produce mere results, and more patient waiting on nature. There were fewer hurried publications of distracting and ephemeral novelties than assail us to-day.

Let it be noted that empiricism has often anticipated science in medicine, and by affording suggestions for profitable research played an honourable part, which it is certain to continue to do in the future.

THE DOCTRINE OF THE DIATHESES.

I pass on next to consider the true relations of experimental research to modern medicine. As I have already stated, I regard the clinical laboratory as one of the best and safest equipments in our new schools, especially because it is in touch with the living patient. It is as human as it can be. (Do not imagine that I am an antivivisectionist.)

The tendency of laboratory training is to lead to the belief that there is a constancy in each unit of humanity, presenting similar proclivities, immunities, and characters in respect of the tissues, metabolisms, and secretions of the body. Yet it does not demand much reflection to indicate that this is not the case. We are not so many ninepins turned off from a lathe out of a block of wood. There are, indeed, infinite differences in human units, and the physician must take due note of them as far as he can. This is entirely a matter of observation relating to varying types of constitution or habits of body, and a recognition of the signs of progressive maladies as expressed in the face and the body generally. A trained student of these varied indications may thus acquire a remarkable insight into the ailments and tendencies of a patient without asking a single question, and so is often rapidly put on the track of the conditions he is likely to meet with.

The teaching of the doctrine of the diatheses, or inherent qualities of bodily texture, is not only now set aside but regarded as effete and useless, and thus a whole chapter of our art is closed to modern students. Half an hour spent once a week with a skilled teacher in physiognomical diagnosis, with proof, or disproof, of the opinions thus formed, corrected by inquiry and physical diagnosis, would prove of great service to senior students, and equip them for accuracy in practice. The eminent French physiologist, Charles Richet, has recently called attention to what he terms "a humoral personality which renders each different from other individuals." Remarking on this, Professor Chauffard, in his remarkable address to the International Congress of Medicine last August, declared that "the findings of modern clinical medicine approximate to and complete the teachings of tradition, and suggest the close connexion of these 'humoral personalities' with the old doctrine of the diatheses."[1]

The Arthritic and Scrofulous Habits.

These inquiries are often fruitful. I can give no more pregnant examples of this study than are afforded by the basic arthritic habit of body, and the strumous or scrofulous habit. In the arthritic habit, or diathesis, we find a specific readiness for infection by the peccant bacteriological elements which induce rheumatic fever in the earlier decades of life. Later on we find in this class a marked tendency to the perverse metabolisms which engender gout and the protean phases of that specific malady. The strumous habit of body, with its two varieties of refined and coarse physiognomies, presents us with a soil which is the most favourable of all for the cultivation of the bacilli of tubercle, and for most of the vicious microbes we have knowledge of. A close study of these two distinct habits of body indicates that there is a remarkable antagonism between them. The arthritic diathesis provides the worst possible soil for the tubercle bacillus, which can hardly lodge or develop in it. The scrofulous soil is little friendly to rheumatic infection, and rarely disposed to the morbid metabolisms issuing in gout.

When these two habits of body blend, as often happens, by heredity, we note that the arthritic element in the individual has a marked and valuable influence in restraining the onset of tuberculosis and of inhibiting its progress if it alights on the body. I must add here a note to the effect that I utterly deny the teaching of those who maintain that scrofula is a manifestation of tuberculosis, or,

[1] THE LANCET, August 9th, 1913.

as is sometimes declared, on the authority of Koch, an attenuated tuberculosis. It is possible to be scrofulous throughout a long life without manifesting overt or serious tuberculous disease.

Heredity.

Closely allied to this line of thought and experience is the study of the doctrine of heredity, a matter always demanding inquiry, aiding much both in diagnosis and prognosis in every patient. Diathetic proclivities may thus be traced in families, the accentuation of some or the outcome of blended habits being noted in various descendants. We thus gain knowledge which is little likely to issue from scientific or experimental work in the laboratory at the present time. I can conceive a time, however, when the specific qualities of tissue and metabolism pertaining to the subjects of different habits of body may be disclosed to us by biochemical and other researches.

I may mention here that Dr. Nathan Raw, of this city, has lately brought forward important facts which give support to some of these contentions.

THE VALUE OF CLINICAL ACUMEN AND OBSERVATION.

I would illustrate the superiority of clinical acumen to laboratory research by a reference to the teaching of the physiologist in respect of the effects of alcohol as he observes them after proceeding to poison certain small animals with this agent. He declares it to be toxic in any degree for all the tissues of the body. As clinicians we have learned to value it both as a food and a valuable therapeutic aid for certain conditions of disease. We claim no scientific authority for its use, but are convinced of the benefits derived from it when appropriately employed. I suppose that no one is better informed than the physicians as to the effects of misuse of alcohol on the body, and such knowledge makes all prudent practitioners duly careful in prescribing it. I have lived long enough to have witnessed great changes of opinion in this matter from the time when alcohol was largely used, to the present day when its total withdrawal as a remedy is urged upon us. I regard both of these methods as erroneous, and illustrating improper practice. The true physician never sails on any prevalent wave of fashion in therapeutics, but endeavours to see all matters in due proportion, with a level head and vigorous common sense; and when common sense is not combined with clinical practice I am sorry for the patient. I may add on this point that I have yet to learn that any lesions specifically attributable to the use of alcoholic liquors have ever been noted in the necropsies of persons who have led temperate lives, and employed such articles in strict moderation.

While we welcome new methods and post-graduate teaching of them as essential to the progress of medicine and the better equipment of the practitioner, we must acknowledge that in many fields of practice there must be few opportunities of employing them. Hence the value of well-trained observation and clinical acumen which must remain, not seldom, all that can be drawn upon in such circumstances. It is, however, desirable that fresh knowledge should be acquired even by those who are unable to employ it, so that they may urge its benefits on such patients as may be able to secure them elsewhere.

Even in the most favourable environments we do wisely to hold by our clinical skill amidst the temptations of these days to make short cuts in diagnosis, when, without due meditation and patient examinations, we may even defer to make one at all, and proceed at once to arrive at it by securing a direct view of the "living pathology" of our patient somewhere within the recesses of the body. Such a practice is now possible, but it leads to a decay in our clinical art, and it is surely undesirable if not imperatively called for.

We must all regret the injury that has been done to careful clinical study and skill by the National Insurance Act. I would ask, Of what avail is it to provide the best teaching for many of our pupils who cannot by any possibility make proper use of it in the toils of panel practice? The public has little knowledge of the serious blight that has thus fallen upon our profession by this ill-conceived scheme, one that could not have been thrust upon it if it had stood shoulder to shoulder in resisting it, both in the interests of the public and of the honour of the profession.

I need not allude to the value of well-prepared formal clinical lectures, illustrated, when possible, by exemplary cases, but I would urge the importance of holding weekly consultations with the whole staff of physicians on certain patients presenting difficulties in diagnosis. These should be held in a theatre, and the patients examined in the presence of the pupils. The several opinions formed should be declared after the removal of each patient. One of the great advantages of our British clinical teaching is that it brings every student in contact with the patient, and leads him to investigate for himself and take his own notes. Continental teaching does not secure this.

Evaluation of Therapeutic Methods.

The new methods of vaccine and serum therapy, and the employment of salvarsan and other powerful agents demand watchful study and large experience of them before we determine their precise and appropriate employment. We have to reckon with impatience on the part of the public which takes note of startling new remedies, and expects an immediate and accurate use of them at our hands.

It is sometimes forgotten that in the matter of treatment clinical observation must always be the final appeal. As declared lately by Professor Chauffard, "it is the physician at the bedside who has the last word to say, and he controls all therapeutical methods, whether old or new. It is by clinical observation alone that the newest acquisitions are to be judged as fruitful or consigned to oblivion."

The Inherent Vitality of Patients.

Once more, what an interesting study awaits us in the endeavour to ascertain the degree of inherent vitality in our patients. The varying tissue-resistance of the body is truly remarkable, a personal element in each case. We seek to explain the contrast in the gradual wear and tear of the textures observable in the still-active nonagenarian with that of the obvious senility of some who have not reached far beyond middle life, and who have yet lived prudently. This inherent vitality is a great element to be reckoned with. It is sometimes familial and racial, and is an appanage of the Hebrew race. It materially affects our prognosis in cases of acute and chronic disease. Disregard of this factor probably accounts for more gloomy prognoses than are justifiable, the vital resistance of the individual not having been appreciated. Such condemned patients are occasionally found to provide material for "faith" and "spiritual" healers to exult over and publish to our discredit.

We have lately been reminded by a great clinical authority that "book prognosis" is far removed from the living and actual prognosis applied not to the disease but to the patient.

The Mental State of the People.

The modern clinical teacher should take note of the changes which occur in the mental disposition and conduct of his patients as time passes on. We are led to inquire in this connexion if, with what we are pleased to call progressive civilisation, our people are really more brave and patient than were our ancestors of a century ago. I incline to the opinion that the introduction of anæsthetics and numerous anodynes, the pressure, strain, and motorial life of our population may, in varying degree, account for the present phase of tenderness, introspection, impatience, and mawkish sentimentality which is now so prevalent. These conditions certainly modify the symptoms and tend to disturb the treatment of our patients. The clinical laboratory will not help us in dealing with such matters. Our public school doctors now tell us of the "nerviness" of many schoolboys who fail to display the pluck and hardness of their predecessors.

If we take note of these matters it is a duty for us to declare them. They are very manifest, we are told, in the United States of America, and are attributed to similar causes prevailing in large centres. Higher education has not only not averted the onset of these phases, but has probably rather encouraged them. The introduction into our daily press of medical matters with detailed descriptions of diseases, together with vulgar pictures of scenes which it were better not to depict, is having, as I believe, unwholesome effects upon the public, rendering people less courageous and amenable, and vastly more apprehensive when they become patients.

I think we owe a duty to the public in referring to these sources of mischief, and we, happily, can do so apart from all debasing political considerations. You may think that I have wandered from my text in alluding to these conditions now encountered in our patients. On the contrary, they are serious clinical matters, as many of us know well.

THE MODERN TEACHING OF CLINICAL MEDICINE.

To sum up, I will now endeavour to point out what manner of man a modern teacher of clinical medicine should be. We find some new suggestions on this subject in the recent report of the Royal Commissioners on the University of London. These recommend the adoption of the system followed in the great schools of Germany. This, put briefly, presupposes a fully trained physician who should devote his life mainly to teaching, dealing with a sufficiency of hospital in-patients, together with a staff of expert assistants working in a laboratory attached to the wards. The professor is to be debarred to a large extent from entering into any private practice or consulting work.

Such a system would completely overturn our present methods, and several objections to it promptly occur to us. One of these, and an important one, is the limitation of duty mainly to hospital in-patients whose ailments are always the most serious. One of the greatest advantages of our British system is the wider experience to be gained from private practice which is wisely permitted, one which admits of knowledge gained from the study of many morbid conditions which are seldom seen in hospital in-patients. Our well-conducted out-patient departments, of moderate size, with skilled teachers, constitute one of the best sources of experience for all students of medicine. Another objection is the difficulty of finding such men in this country who will be able and ready to forego the emoluments derived from private consultations. In default of this, it would be necessary to have such appointments liberally endowed, and with pensions on retirement, from some source other than the medical school, which has no funds to employ for the purpose. Again, the expert staff of senior men attached to such a professor must also be liberally paid for their services, which should be carried on for some years, as they are in foreign schools, by the same men.

I am prepared to deny the special advantages which are claimed for this system. According to my ideas, it is not clinical teaching in its best sense. It appears to be propounded with the idea that medicine is, or ought to be, an exact science, and hospital patients little else than materials for the laboratory. That is not my outlook in this matter. I maintain that such professors would not be the best instructors for the average student —that is, for the majority of medical pupils; and I go further, and declare that the system now followed in our best British schools produces superior and more useful clinical practitioners than can be found as the products of many of the continental schools. Our teachers have the widest scope for their experience. Their duties demand and receive much time, and in all good schools, regulated by discipline, the best teachers expend much time in their wards. We are told, however, that "the chief object in London medical education is the passing of students through the various examinations." I must beg leave to deny this assertion in respect of the hospital physicians of the London, provincial, and the Scottish schools. I have taught pupils for more than 30 years at the bedside and lectured in a large school of medicine, and I can affirm that the idea of preparing them to pass examinations has never once entered my head; my duty has always been to teach them how to practise their profession with insight and skill and to promote accurate observation of the details, as well as of the greater facts, in evidence, away from all book studies. I must leave the surgeons to speak for themselves in this matter.

Post-graduate Training.—Chiefs of Clinics.

So far I have been considering the opportunities available in this country for educating the average practitioner. It has lately been declared in the public press that there are no provisions for aspiring students and for those who have the ambition to fit themselves for the higher position of teachers. Such advantages are certainly not far to seek in our largest schools, and the men we are thinking of may safely be left to avail themselves of them. There are now excellent post-graduate schools and laboratories for research in all our great cities, and colonial and foreign students are making use of them. It is natural and desirable that pioneers such as these should seek inspiration and fresh fields of work in the great continental schools, and learn other methods from their eminent teachers. It must be added that those who conduct such teaching in this country are, as a rule, very inadequately remunerated for their laborious duties. In the continental schools there is provision made for them by Government grants

The public little realise that some of our best hospital teachers are actually contributing out of their earnings towards the compulsory education of students. We do not hear of similar benefits being bestowed in other professions.

I think that it would be an advantage to our system of hospital training if we introduced the foreign one of securing a chief of the clinic to act under each clinical teacher, who should undertake and supervise the research work of the clinical laboratory. These appointments should be made for a term of three years at least, and an adequate stipend should be paid to the occupant. The experts in the laboratory should always endeavour to be in touch with the patients who become subjects for research. Beyond this, I hope that our British schools will not follow further on foreign lines in the endeavour to improve our teaching.

CONCLUDING REMARKS.

I confess to the highest admiration of many of the methods pursued in the Parisian school, for there we find the art of medicine bound up with the best scientific side of it. The great clinicians there have the benefit of the fuller experience of private practice and consulting work, and they certainly devote themselves assiduously to their duties in the wards.

A clinical teacher has great responsibilities. Before all things he must be human and sympathetic, never forgetting that he is dealing with patients who have souls as well as bodies, and not with mere "cases." He has to illustrate and teach good manners as well as medicine. He must believe in his art, for a sceptic in therapeutics can teach nothing. He should not pursue many novelties, for in my experience novelty-hunters have not been well instructed in the principles of medicine in their early career. To these requirements I would add, lastly, a large measure of tact and common sense, no small amount of geniality and humility, and a due degree of such dignity as rightly belongs to men charged with serious duties to their country and their fellow creatures.

THE TREATMENT OF NEURASTHENIA.[1]

BY J. S. RISIEN RUSSELL, M.D. EDIN., F.R.C.P. LOND.,

PROFESSOR OF CLINICAL MEDICINE AND PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE.

Diagnosis.

"Neurasthenia" has become as much the refuge of the destitute, when a diagnosis is called for to account for nervous manifestations, as has long been the case with "influenza" when febrile symptoms are under consideration.

There can be no doubt that in many instances the diagnosis is made owing to the kindness of heart of the medical man responsible for it, as, although fully alive to the fact that he is dealing with a case of insanity, in which melancholia, delusional insanity, or some other mental affection is really responsible for the patient's symptoms, he allows himself the licence of labelling the affection "neurasthenia" for the comfort of the relatives and possibly for the peace of mind of the patient after he or she has been restored to health.

An individual who is really suffering from hysteria is similarly commonly said to be affected by "neurasthenia," as hysteria is an ugly word and one that is not usually palatable. Then, again, I need hardly remind you how often some grave organic affection is in the background, underlying the manifestations ascribed to neurasthenia, and how in some instances it is only at the necropsy that the real nature of the affection is ascertained.

Even after we have eliminated all such cases that have no legitimate claim to the diagnosis of neurasthenia we are left with a very large collection of patients whose symptoms are very similar, but with regard to whom it is justifiable to speculate that probably many very different maladies are confused in the present state of our knowledge. We hear so much of colitis, intestinal stasis, and other conditions as giving rise to a group of symptoms that some of us ascribe to neurasthenia that it becomes all-important that we should attempt to determine whether these conditions are the outcome of neurasthenia or whether they are responsible for the symptoms ascribed to neurasthenia. Are we to rely in treatment on measures calculated to raise the tone of the nervous system to effect a cure, or is the remedy to be found in Plombières douches, liquid paraffin, abdominal supports, or possibly evisceration?

Types of the disease.—After eliminating all other possibilities and justifying to our satisfaction the diagnosis of neurasthenia, we are next face to face with the fact that there are many different types of this affection, and that it is very necessary to recognise this if treatment is to have any chance of success in a given case. Without multiplying types unnecessarily it will probably be admitted by most of us that the cases fall conveniently into one of three main groups—a cerebral, spinal, and cerebro-spinal—and that the first group may be further conveniently subdivided in view of the fact that in some of the patients the symptoms are physical, whereas in others they are purely psychical, although in many both physical and psychical symptoms obtain.

To justify these contentions I need only briefly remind you of the headache, vertigo, and other purely physical symptoms that belong to one variety of the cerebral type, and of the phobias, obsessions, and other mental symptoms that belong to the other; of the feelings of physical exhaustion, pains in the back, weakness of the legs, and other similar symptoms that belong to the spinal type; and to the cases that constitute the cerebro-spinal type in which cerebral and spinal symptoms obtain in the same individual. Certain it is that these different types must be recognised if neurasthenia is to be treated with any hope of success, and that what may reasonably be relied on to succeed in one type of case cannot possibly be expected to effect good in another.

In addition to all this the nationality and temperament of the individual must be given due weight in our deliberations before we recommend treatment, considerations that are little, if at all, less important than the question as to whether the symptoms indicate a degree of exhaustion of the nervous system in which the tone is very low and in which the senses are blunted, or one in which the nervous system is in a state of undue tension with irritability and hyperacuity of the various senses. To attempt to treat people of all nationalities and temperaments on the same lines is to court failure, and it is equally certain that much in treatment that may benefit the individual with

[1] Being a paper read at the Medical Society of London on Nov. 10th, 1913.

marked loss of tone of the nervous system is not only calculated to do no good in the patient whose nervous system is in a state of over-tension, but that such treatment usually does much harm.

Causes.

In neurasthenia, as in other maladies, it is, of course, important to search for the cause, and when this is possible to remove it. It is, however, a mistake to suppose that removal of the cause, when this can be effected, will suffice to bring about a cure, for this is far from the truth. Nevertheless, careful search must be made for any possible cause such as some remote source of septic absorption from the pelvic organs of the female, a chronic appendicitis, pyorrhœa of the gums, &c.; chronic constipation, colitis, and dyspepsia must be corrected, as must all such prejudicial influences as eye-strain and the like. People suffering from this malady usually require active treatment directed towards resting and toning up the nervous system, in addition to the removal of the cause that has been responsible for the condition. I say active treatment for the reason that I am fully satisfied that in the large majority of cases rest and change without active treatment merely result in temporary amelioration of the symptoms, and that without active treatment the majority of patients relapse soon after they return to their normal conditions of life. True as all this is, it is equally certain that the degree of success to be expected from treatment in neurasthenia is largely influenced by the cause that is to be blamed for inducing the condition.

Prognosis.

The subjects of neurasthenia commonly regard themselves as suffering from some peculiar malady distinct from anything that has ever affected anyone else, and they are usually most hopeless in regard to the outlook, and so most sceptical as to the chances of a cure. This is, of course, not justified in a large proportion of cases, but in others we know only too well that, although the patient is wrong in supposing that he or she is suffering from any peculiar affection, nevertheless there is unfortunately good ground for the belief that the outlook is hopeless and that no treatment is to be expected to effect a cure.

Of no other class of case of neurasthenia is this more true than of the variety in which an individual is born with the tendency to the affection, and in whom sooner or later the symptoms will appear without any adequate cause that can be assigned, such as undue strain, shock, or any of the ordinarily recognised causes that are known to induce the condition. In this class of case the history is often very similar to that with which we are familiar in "folie circulaire," for periods of exhaustion with depression alternate with periods of feelings of exhilaration and wellbeing, in which there is an exuberance of spirits. Another class of case in which the outlook is far from promising is that in which, either with or without an adequate exciting cause, there is in the background a hereditary neuropathic taint which exercises a profound influence on the patient's illness, and which militates very seriously against the chances of success from treatment.

Despite all this, there remains a very large group of cases of neurasthenia in which a cure is to be confidently expected if the proper treatment can be secured for the patients, and one of the essentials in the treatment is a hopeful outlook as regards the future on the part of the medical man who is prescribing or carrying out the treatment. So much does this mean to every neurasthenic that it is our duty to extend this mercy to all cases of the kind that come under our notice, even if we have reason to fear a contrary result, for the temporary mental comfort and possible alleviation of suffering more than justify this.

Cases in Children.

The larger my experience of neurasthenia the more am I convinced that children suffer from this affection, and that many a neurotic wreck that we meet with in after life might have been made very different had his malady been recognised and properly treated in childhood. I recognise very fully how difficult it must be at times to be sure that we are dealing with a genuine case in which lack of nerve tone is responsible for the child's behaviour, as contrasted with laziness or malingering. Nevertheless I am convinced that many a boy is being flogged or otherwise punished to-day in consequence of what is as much an illness as any other malady from which he might be suffering, and it has been my happy privilege to help many such young patients, sometimes in the face of strong opposition from schoolmasters and medical men. More often, however, I am glad to say that no opposition has been placed in my way, although it has been painfully obvious that I have been regarded as a "specialist" with little knowledge of boys and their ways, and thus easily taken in by the lazy boy or girl who feigns symptoms of illness in order to escape from the drudgery of work.

Few things have given me greater pleasure than in one such case in which I was able to send a telegram of congratulations to a boy in consequence of a brilliant athletic achievement for his school, a boy who a year or two before was in a condition in which nothing of the kind would have been possible, but who under appropriate treatment made such an excellent recovery as to enable him to distinguish himself in this way.

When the diagnosis is made in these young people I feel confident that the correct treatment in them is a properly conducted "rest cure." In those who have not yet commenced school life this can be done in the patient's own home, if he or she be properly isolated with a good nurse-masseuse who is thoroughly conversant with the details of the treatment. When, however, the patient is at school the cure ought to be conducted in a good home where the treatment is well understood, and in the case of boys it is all-important to select a home where a resident medical man is at the head of affairs, and where in consequence the boy will not be only under petticoat government. The reasons why we should insist on treatment away from the patient's own home in such cases are too obvious to call for further comment.

Treatment.

This leads me to deal with the treatment of neurasthenia in general, and I make no hesitation in at once asserting that in the large majority of cases there is no other method of treatment that offers the same chances of success as the so-called "rest cure," provided it is conducted in a home given up to treatment of the kind, where the atmosphere is impregnated with all that goes to make for success in the treatment, and where the medical man, matron, and nurses all thoroughly understand

such patients and know how to deal with them to their best advantage.

Can it be wondered at that this method of treatment so often fails, and in consequence falls into disgrace, when medical men are content to conduct their "rest cures" in homes where the din and clatter of preparations for operations, the smell of chloroform or ether, the groans of sufferings or other ominous sounds that make it only too evident what is happening, so constantly reach the patient, and where the nurses delight in regaling them with the most gruesome details of the latest operations, or of some "interesting" surgical cases that they have nursed in the past?

Personality plays so important a part in the treatment of neurasthenia that it is highly necessary to secure people who, while sympathetic, have nevertheless sufficient force of character to inspire confidence in the patient. One of the first essentials towards the successful treatment of these cases is complete confidence in the person who has prescribed the cure, and in those who are to carry it out. The person who belittles the neurasthenic, or who scoffs at his symptoms, courts failure in the treatment of the case. The attitude to adopt is that of sympathetic attention to the detailed account of his case, and a judicious question interposed from time to time does good, as does a suggestion that this or that symptom exists, for this naturally allows the sufferer to recognise that the person he is consulting is familiar with the symptoms that are to be expected in a case like his, which proves helpful when the time comes for the medical man to try to convince the patient that he is not suffering from anything peculiar or incurable, but that many hundreds of other people have suffered in a similar fashion and have been cured by appropriate treatment.

Much patience is naturally called for in all this, and it is difficult to conceive a moment when it can be more difficult to exercise such patience than when at the end of a long and tiring interview of the kind, with the hospital to attend, a train to catch, or a peppery practitioner to meet in consultation, the proverbial list is extracted, and consulted so as to allow the patient to make quite sure that he has not omitted to mention any important symptoms. A supreme effort is then necessary, and rather than show in the least that we are in a hurry it is better to ask for a second opportunity of going more fully into so important a case, so as to avoid the risk of failing to gain the confidence of the patient through any show of irritation, if success is to be expected to follow the advice we intend to give in regard to treatment.

In addition to the particular class of cases already referred to in which it commonly happens that no form of treatment proves successful, there are others in which a "rest cure" alone, unaided by certain adjuncts in treatment, cannot be expected to do all that is required in the case. There are other cases in which the temperament of the individual makes it impossible to hope for good from the unmodified method of treatment that bears the name "rest cure," others in which the physical condition of the individual does not warrant the hope of success from this method of treatment, and others again in whom the symptoms are so purely psychical, and the physical condition of the patient so good, that there is no reasonable probability that a "rest cure," no matter how prolonged, will do any real good.

Here it is that "suggestion" finds its most useful place in the treatment of neurasthenia. Whether this method of dealing with a given case is to be recommended alone, or whether it should be combined with other methods of treatment, directed towards building up the tone of the nervous system, must depend on the exact combination of symptoms that obtain and on the physical state of the individual. Happily much of the prejudice against this method of treatment that has existed in the minds of the public and members of the medical profession is being gradually removed, and the rooted conviction that if once a patient gives up his "will power" to a hypnotist he is no longer a free agent, but is doomed to be constantly under the domination of the will of the operator, is fast losing the formidable hold it has had on the minds of people. In consequence of this many a sufferer from phobias and obsessions is able to-day to secure relief from a method of treatment that has been denied to others similarly afflicted in the past, and even to many at the present time.

I must leave it to those specially qualified to speak with authority on such matters to deal more fully with this aspect of our subject, but in so doing I cannot help allowing myself the liberty of questioning how far it is wise to probe too deeply into a forgotten past, and as to whether Freud's method of psycho-analysis has not certain limitations that must be recognised if a method of treatment that can help some is not to bring uncalled-for misery to others.

Massage and the application of faradic electricity form part of the usual routine in the ordinary rest cure, but there are patients who are not helped by massage, as it proves too irritating to them, aggravating all of their symptoms and increasing their insomnia when this happens to be a symptom. What is true of massage is applicable to electricity in a much larger proportion of cases in which this method of treatment proves much too stimulating, and is accordingly calculated to do harm rather than good.

One sees so many cases of neurasthenia in which the patients have been treated by massage without being told to rest in conjunction with this treatment, that a word of warning in this connexion does not appear to be out of place. Massage should be only employed in these patients if an adequate amount of rest can be secured during the course of treatment, as otherwise it is calculated to do harm in the majority of cases. The same does not apply to electricity, which can often be employed to advantage in one form or another without its being necessary to insist on rest in the way that is called for with massage. More than this I do not propose to say about this form of treatment, as there are those who are to take part in the discussion whose special knowledge of this subject will permit of their speaking with a degree of authority that I cannot claim.

Of hydropathic methods the pack and warm bath find a place, especially in the treatment of insomnia; while the needle bath and spinal douche, which are useful in many cases of neurasthenia, are especially so in the sexual and in the spinal forms of the affection.

A useful adjunct, and one which is sometimes successful when employed without any other form of treatment, is spermin, alone or combined with various glands of internal secretion. While useful in all forms of neurasthenia, and especially so where there is loss of sexual power, one or other of these preparations has appeared to be helpful

in rescuing from cerebral softening the neurasthenic of advancing years, in whom there has been reason to suppose that the cerebral vessels have been none too good and have in no small measure been responsible for the calamity that seemed pending.

Drugs must take an entirely secondary place in the treatment of neurasthenia in so far as a cure is to be expected from their use, but certain of them prove helpful in mitigating the sufferings of these individuals. Tonics often do far more harm than good, and a drug like strychnine behaves in much the same way as electricity in many a case of the affection, and is especially to be avoided where insomnia is a prominent symptom. It, however, finds a useful place in the treatment of sexual and of spinal neurasthenia, and may sometimes be employed with advantage in other forms of the malady when judiciously combined with some sedative such as bromide, a drug that we could ill afford to dispense with in the treatment of this affection. Even in spinal neurasthenia, however, the degree of irritability may preclude the use of strychnine and electricity in the treatment.

Provided it is tolerated by the gastro-intestinal tract arsenic is one of the most useful tonics that can be employed in the treatment of these patients, while glycerophosphates, lecithin, phytin, and in some cases iron, all find a place among the medicines that prove helpful in some cases, but the last-named is usually badly borne by the stomach and is apt to increase the tendency to constipation.

All that need be said of hypnotics is that we should avoid their use as far as possible, but that it is better to secure for the patient a good night of sound sleep from time to time rather than allow him to go night after night without any such relief, and that of the various hypnotics that may be tried medinal and trional prove as useful as any, while morphia should be avoided at all costs, although I was once driven to its use most reluctantly, with the best possible results, in a man who was becoming delirious at night after a prolonged period of insomnia unrelieved by every other hypnotic that was tried.

Medicines also prove helpful in correcting dyspepsia and constipation when other measures in treatment, such as diet, massage, and electricity, have failed to do what is required. An alkaline mixture directed towards combating indigestion is a useful adjunct in the treatment of patients who are undergoing a "rest cure," and in addition to any ordinary aperient that may be found necessary to secure a daily action of the bowels, it is well to prescribe for such patients blue pill or calomel once a week, followed by a saline.

The treatment that is to follow a "rest cure" is little less important than the cure itself. Various forms of mental and physical exercises, including walking and other kinds of exercise in the open air, must now be alternated with periods of rest in the recumbent posture, and any such exercise, whether mental or physical, must be taken short of its inducing undue fatigue. The periods of exercise should be gradually lengthened as the periods of rest are curtailed.

Now it is that other methods of dealing with these patients, such as by change of air, sea voyages, and the like, that usually prove failures before active treatment has been carried out, find a useful place in the cure of cases of neurasthenia. In selecting a place for change of air there can be no doubt that the large majority of neurasthenics do far better at inland bracing places than by the sea, although there are those who benefit by residence at the seaside. In the choice of an inland resort due attention must be paid to the fact that where insomnia is a symptom the higher altitudes of mountainous countries like Switzerland are to be avoided, and the same applies when the heart is irritable with a tendency to palpitation.

Wimpole-street, W.

NOTES ON FOUR CASES OF URETERAL CALCULUS

IN ONE OF WHICH A COMPLETE CAST OF THE URETER WAS PRESENT.

BY HAROLD COLLINSON, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, LEEDS GENERAL INFIRMARY.

BY improvements in radiography and a more general use of the cystoscope the diagnosis of calculi impacted in the ureter has been simplified and operations for their removal have become increasingly frequent and successful. The number of recorded cases is very large, and little that is new can be said in reference to the methods of operative treatment. I have recently had under my care four cases which present interesting features, one of which I believe is unique as regards the size of the calculus removed, and for that reason I feel that they are worthy of record.

CASE 1. *Calculus impacted in the upper end of the ureter; calculous anuria; nephrotomy.*—The patient, a man aged 40, was admitted to the Leeds Infirmary, under the care of Professor H. Littlewood, on Nov. 10th, 1910. About seven years ago the patient, who had previously enjoyed perfect health, began to be troubled with "gravel stones." He said that during the next five years he passed a stone on the average every six months. Two years ago he was about to be admitted to the infirmary, but two days before he had to come he passed a stone of the size of a pea. From that time until seven weeks ago he was quite well, but then was seized with pain in the left renal region and passed a quantity of blood; he continued to work for a fortnight, but then ceased work and the hæmaturia disappeared. A return to work was followed by a recurrence of the pain and he came to the infirmary. On admission the urine was acid, of specific gravity 1010, with a slight trace of albumin, but no blood. A careful screen examination was made by Dr. L. A. Rowden, the director of the electro-therapeutic department, but no shadow could be detected in either kidney or ureter. No operation was advised, and the man returned home on Nov. 10th. Between that date and Jan. 5th, 1911, he was free from symptoms with the exception of an occasional slight pain in the left loin. On the morning of Jan. 5th he had an acute attack of pain in the left renal area followed by profuse hæmaturia; the same evening he found that he could not pass urine although the pain was much easier. Between that time and his readmission he passed no urine at all.

On readmission on Jan. 7th the patient looked well, the pulse being 72, and the temperature 97·5° F. There had been no vomiting; his mental condition was normal. A catheter withdrew no urine. Various diuretic drugs were tried without result. X ray examination again gave no evidence of calculus in either kidney or ureter. Between the 7th and 10th no urine was passed; there was no vomiting, and with the exception of slight headache he complained of no symptoms. The pulse-rate fell to 60 and the temperature to 97°. Professor Littlewood kindly asked me to see him on the morning of the 10th, and I decided to explore the left kidney.

A lumbar incision was made. The kidney was found to be much hypertrophied, acutely congested, and slightly hydronephrotic. Owing to the risk of lacerating the organ in its acutely congested condition it was thought unwise to attempt to deliver it through the wound, so the pelvis and ureter were explored *in situ* with the finger. A calculus was felt to be

filling the upper end of the ureter and projecting into the pelvis. An incision was made on the convex border of the kidney and a finger passed into the pelvis and the calculus, which was of the shape and slightly larger than a date stone, removed. The kidney was drained by a rubber tube passed through the cortical incision. Within five hours the dressings were soaked with blood-stained urine, and at 10 A.M. next day the patient passed 4 oz. of urine naturally. Urine ceased to leak from the wound in a week, and from that time onward the amount of urine passed varied from 24 oz. to as much as 74 oz. in the 24 hours. Recovery was uneventful.

Chemical examination of a portion of the calculus demonstrated that it was composed of practically pure uric acid and it was almost transparent to the X rays, for a screen examination of the stone placed beneath a thin book scarcely revealed a perceptible shadow.

I was naturally anxious to ascertain the condition of the man's right kidney, but thought that the risk of a cystoscopic examination so soon after a complete suppression was unjustifiable. During December, 1911, however, I sent for him and found that he had been following his employment as a miner for some months with no inconvenience, except occasional backache. He consented to come into the hospital for cystoscopy. The appearances were as follows.

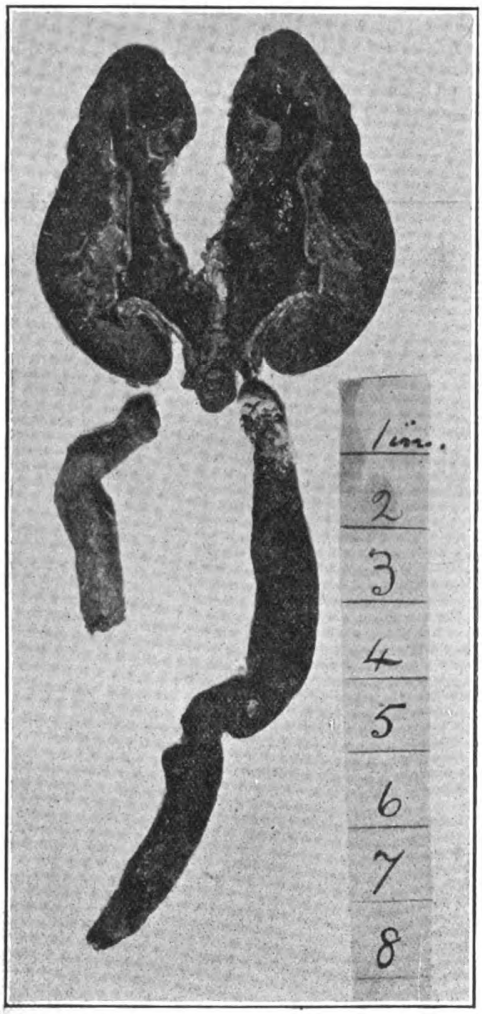
The left ureteral orifice was prominent and slightly patulous, with some reddening of the lips. Within 20 minutes of the injection of 1 drachm of 4 per cent. indigo carmine vigorous and frequent jets of deeply blue-stained urine were being ejected. The right ureteral orifice was narrow and slit-like and almost invisible; an occasional muscular contraction could be seen, but during the 15 minutes it was under observation no jet of urine was detected. The conclusion to be drawn is that the right kidney is almost if not entirely functionless. The urine contained a small quantity of albumin and a few pus cells. Within six hours of the cystoscopy the patient had two smart rigors and his temperature rose to 104°, but he was fortunately quite well again in 48 hours.

The case illustrates in a striking manner the remarkable absence of toxic symptoms in obstructive anuria and a difficulty which may arise in deciding upon which kidney to operate. If the localisation of pain had not been so definite the absence of X ray evidence of calculus would have made the decision extremely difficult, and it might have been necessary to explore both kidneys. In these circumstances the prone position recommended by Deanesly[1] would have been of great convenience. The permeability of the stone to the X rays is a circumstance of much interest, for at least two examinations were made under the best possible conditions and the stone was of considerable size. There is no doubt that in cases with definite clinical symptoms pointing to renal calculus a negative X ray examination even by an expert is not a contraindication to operation, for the stone may be quite impossible to detect by such means.

CASE 2. *Calculous cast occupying the whole length of the ureter; nephrectomy and ureterectomy.*—The patient, a female aged 29, was seen in consultation with Dr. Allan R. Wilson, of Leeds, and Dr. Rowden. A skiagram had been taken by Dr. Rowden. (Fig. 1.) This remarkable picture shows two shadows, one extending from the lower pole of the left kidney to the brim of the true pelvis, and the other from this point to the opening of the ureter into the bladder. Apparently two calculi are present, one articulating with the other at a point where the ureter makes a sharp turn over the pelvic brim. Examination of the right kidney was negative. The patient gave the following history. Her mother told her that at the age of 4 years she had a sudden and violent attack of pain in the left kidney region and that she subsequently passed a quantity of blood; this was followed by similar attacks of pain coming at intervals but not always accompanied by hæmaturia. At the age of 12, as the attacks persisted, an X ray examination was made, and although a calculus was diagnosed no operation was advised. Shortly afterwards she went to Scarborough, and whilst there had a number of attacks with considerable hæmaturia; she was confined to bed for several weeks and was evidently extremely ill. After her return the attacks persisted and she frequently had to be sent home from school on account of pain. At the age of 22 she became a barmaid, and although she often had to lie down and occasionally to return home during an attack she managed to keep her situation. The pain appeared to be typical renal colic, beginning in the

FIG. 1.

Skiagram from Case 2 showing calculous cast of left ureter, from behind.



kidney region and radiating to the groin, not infrequently accompanied by vomiting and usually followed by more or less hæmaturia. A long walk, hurrying, or prolonged standing would almost always precipitate an attack. So far as she was aware she had never passed a calculus naturally. During the last 12 months she had had several attacks of severe hæmaturia.

On examination she was seen to be a well-nourished girl, but distinctly anæmic. The left loin was tender, but the kidney was not palpable. In the position of the ureter, however, a hard tumour could be felt; this extended from the renal fossa to the brim of the pelvis, it followed the line of the ureter, was tender on pressure, very hard, and was apparently fixed against the posterior abdominal wall. It appeared to be about the thickness of the thumb, and the surface was smooth. On rectal examination a similar mass could be felt in the termination of the left ureter; its lower extremity was pointed and could be moved slightly from

[1] Brit. Med. Jour., 1911, vol. i., p. 1041.

side to side by the finger. It was evident that we had to deal with a calculus or calculi occupying the whole length of the ureter. The urine was alkaline, and contained a quantity of albumin, pus, and amorphous phosphates. A cystoscopic examination was made 20 minutes after the injection of indigo carmine. The bladder was slightly injected but

FIG. 2.

Photograph of kidney (from Case 2), with portion of ureter and calculus.

otherwise normal; the right ureteral orifice was normal in appearance, and vigorous jets of blue urine were issuing from it. The left ureteral orifice was situated on a mound-like elevation and no blue urine was passed during several minutes, although occasionally a feeble jet of blood could be seen. A ureteral catheter entered without difficulty, but was arrested at a point about half an inch from the orifice It was evident that the left kidney was secreting little, if any, urine, and that the right was sufficiently healthy to warrant removal of the former if this should be found necessary. I did not think it was wise to catheterise the right ureter on account of the infected state of the bladder.

An operation was performed on March 17th, 1911. The kidney and ureter were exposed retroperitoneally through an incision extending from the costovertebral angle to a point above and in front of the anterior superior spine. The kidney was found to be slightly enlarged and hydronephrotic. No calculi could be felt in it. From a point half an inch below the junction of the ureter with the renal pelvis the former was occupied by what appeared to be a calculous cast; the ureter was therefore isolated to the point at which it crossed the iliac vessels and opened by a longitudinal incision over the upper end of the calculus. This was seized with forceps and a piece 4 inches in length removed without difficulty; the lower end had a fractured surface, and after slightly enlarging the incision a further portion 1 inch in length was removed from the ureter where it lay in front of the iliac artery. This piece had a convex facet on its lower aspect which evidently articulated with the stone filling the pelvic ureter. In order to reach the latter it was necessary slightly to enlarge the parietal incision and to open the ureter just above the pelvic brim, and even then its removal was a matter of considerable difficulty, as the edges of the cup-shaped depression on its upper end were sharp and the posterior margin was hitched beneath the brim in intimate relation to the iliac vessels. The stone was steadied by the pressure of an assistant's finger in the rectum and it was removed in one piece, but the ureter, which was extremely friable, was torn almost across at the site of the incision. It was evident that the kidney and ureter were so much dilated and altered and that so much damage had been done to the latter by the operation that it would be wiser to remove them. The ureter was therefore divided as low down as possible and removed along with the kidney. The lower end was wiped out with pure carbolic acid and dropped back, and a small drainage-tube was passed down to it. Convalescence was quite uneventful and the patient is now well.

Fig. 2 shows the kidney, a portion of the ureter, and the two calculi, beside which a scale in inches has been placed. The upper stone is rather more than 5 inches in length, and the lower $2\frac{1}{2}$ inches. The weight of the first is 840 grains and of the second 440 grains, a total of 1280 grains or 83·2 grammes.

So far as I am able to ascertain from the literature the calculus removed in this case is unqiue. It really consists of a cast of the ureter extending from the kidney to the point of entry of the ureter into the vesical wall. A section of the lower calculus (Fig. 3) shows at its lower end a small

FIG. 3.

Photograph of section of lower calculus (from Case 2), showing uric acid stone with superimposed deposit of phosphates.

oval uric acid stone which evidently became impacted during the patient's childhood. Above this successive layers of phosphatic material have been deposited from the urine which was able to trickle past the calculus until the ureter was ultimately filled. A similar specimen is figured

by Morris [2] and is in the museum of St. George's Hospital, but this was discovered post mortem.

CASE 3. *Calculus impacted in the iliac portion of the ureter.*—The patient, a man aged 45, was seen in consultation with Dr. L. J. Milne, of Mirfield, in April, 1911. During the past month he had had two attacks of acute pain in the right kidney region shooting down to the groin. These lasted several hours and were followed by slight hæmaturia. Renal calculus was suspected and an X ray examination was made during the first week in May; a shadow of the size of a small bean was seen in the right kidney and was diagnosed as a calculus. As I was going away from home the operation was deferred until June. At the end of May another severe attack occurred and he was sent to the infirmary. On this occasion no shadow could be seen and he returned home in a few days. Four weeks later he had a fourth attack of colic and was readmitted. A screen examination on July 21st was negative, but as the symptoms were so definite and he was quite sure that he had not passed a stone I decided to explore the right kidney.

The operation was performed on July 24th, when a lumbar incision was made. The renal pelvis was slightly dilated, but no calculus could be detected in the substance of the kidney or in the pelvis on palpation. A small incision was made in the cortex and the pelvis explored with the finger; no calculus could be felt. A ureteral bougie was then passed but was arrested above the pelvic brim; the wound was slightly enlarged and the ureter traced down. About half an inch above the point where it crossed the iliac vessels it was found to be obstructed by a small angular calculus of the size of a pea; this was tightly impacted and could not be moved upwards, so the ureter was incised over it at the point of impaction. The wound in the kidney was sutured and the margins of the incision in the ureter brought together by a fine catgut suture. A small rubber drain was passed down to the neighbourhood of the ureteral incision. During the second 24 hours a slight urinous odour was detected in the dressings but quickly disappeared, and recovery was uneventful.

In this case, as in Case 1, X ray examination was negative on two occasions. The first time the patient was screened I myself saw a shadow which I took to be calculus in the kidney, but it was a larger shadow than would be given by the stone removed, and I am certain that no stone was left behind in the kidney at the operation. On the second and third occasions no shadow at all was visible, and it is easy to understand why a small calculus lying at the point from which this was removed should escape detection, for it was lying in front of the thickest portion of the ilium. The case illustrates the necessity for a thorough exploration of the ureter in all operations for renal calculus.

CASE 4. *Calculus impacted in the juxtavesical portion of the ureter; retroperitoneal ureterotomy.*—The patient, a man aged 23, was admitted to the Leeds Infirmary on Oct. 5th, 1911. At the age of 8 years he had a severe attack of renal colic; there was difficulty in micturition during the attack, but no hæmaturia was noted. Between that time and the date of admission he had a large number of similar attacks at varying intervals, and in none of them was there noticeable hæmaturia. The last attack was six weeks before, and on this occasion pain was severe in the hypogastric region and accompanied by cutting pain in the urethra during micturition. His bladder was washed out on two or three occasions with considerable relief. An X ray examination of the kidney showed no calculus, but just above the point where the ureter entered the bladder wall a very distinct shadow was visible. Dr. Rowden kindly took a plate of this for me; it is certainly about the best X ray picture of a ureteral calculus that I have seen. Rectal examination discovered a hard mass in the position of the lower end of the right ureter.

An operation was performed on Oct. 21st. A cystoscopic examination was made 20 minutes after the injection of 1 drachm of 4 per cent. indigo carmine. The left ureteral orifice was normal; vigorous jets of blue urine were issuing. The region of the right ureteral orifice was œdematous and much injected; the orifice could not be identified and no jets of urine were seen to issue during the time of the examination. As I was anxious to know the condition of the kidney the patient was turned upon his side and a lumbar incision made. The pelvis was found to be dilated but not tense; no calculi could be felt. The ureter was dilated to the size of one's little finger, and its walls were much thickened. Evidently the only calculus to be dealt with was the one in the juxtavesical portion of the ureter. To have reached this by extending the lumbar incision would have entailed an extensive division of muscular fibres, so the wound was carefully closed in layers and the patient rolled over on to his back. With the foot of the table slightly raised the usual "gridiron" (McBurney) incision was made as if for the removal of the appendix, but the abdomen was not opened. The peritoneum was stripped from the iliac fossa to the pelvic brim and the ureter isolated; on tracing this down into the pelvis the stone could be felt tightly impacted just at the point of entry into the bladder wall. Efforts "to milk" the calculus upwards were ineffectual until pressure was made upon it by an assistant's finger in the rectum; then careful manipulation succeeded in moving it up about half an inch to a position in which it could be seen and the ureter incised over it. When this was done and the stone removed it was found to be slightly smaller than the shadow in the skiagram and to be covered with projecting spines which were responsible for its immobility. The incision in the ureter was brought together by two catgut stitches of the Lembert type, and a small drain of dental rubber was passed down into the pelvis. For four or five days slight leakage of urine occurred, but at the end of that time it ceased and recovery was uneventful.

In this case, as in Case 2, the history was a long one, and judging from the large size and thickness of the ureter and the character of the stone it is probable that the latter had been lying in the ureter for a number of years. A skiagram of the stone after removal shows a uric acid nucleus with a laminated outer portion. The removal of the stone by the method adopted was not easy, but the difficulties were not nearly so great as one would imagine. If the calculus had not been so tightly impacted and could have been manipulated up the ureter to a point above the pelvic brim its removal would have been extremely simple.

The operative approach to calculi lying in the pelvic portion of the ureter has been the subject of much discussion, and a number of routes have been suggested and most of them practised. Some of these, such as the sacral and parasacral, are unnecessarily difficult and dangerous, and in the male we must make our choice between the following: the perineal, the iliac extraperitoneal, the transperitoneal, or a combination of the last two. The perineal is only applicable to calculi lying in the last inch of the ureter, and has the great disadvantage that only a very limited portion of the duct can be explored, and the calculus is apt to slip away into the dilated ureter above and be lost, an experience which I have had in attempting to remove a stone through the lateral vaginal fornix. It is a method which I should hesitate to adopt. The choice between the extraperitoneal and the transperitoneal routes is a matter of some difficulty. Sinclair White [3] makes a strong appeal for the routine adoption of the transperitoneal operation and records two very successful cases, and to those who are familiar with abdominal surgery this method has much to recommend it. The ease with which the whole length of both ureters can be palpated and the amount of room and good illumination of the operative field afforded must be counted as very great advantages.

[2] Surgical Diseases of the Kidney and Ureter, vol. ii., p. 450.

[3] Brit. Med. Jour., 1910, vol. i., p. 1.

In cases in which the X rays suggest calculi in both ureters or on the opposite side to that to which the clinical symptoms point, a transperitoneal exploration will clear up the diagnosis, and if calculi are present they can be removed with comparative safety by this route. When a calculus is definitely diagnosed to be impacted in the paraischial or juxtavesical segment, and there is no indication to explore the kidney, a muscle-splitting incision such as I have described is the method of choice, and if the stone is difficult of access extraperitoneally a small incision in the peritoneum will allow of the introduction of the finger to manipulate it into a more accessible position or to fix it during its extraperitoneal removal. This combined method has been adopted by J. H. Gibbon [4] in ten cases with excellent results. By this procedure the amount of traumatism is reduced to a minimum. When a calculus in this position is only diagnosed by attempts to pass a ureteral bougie during exploration of the kidney a separate muscle-splitting incision should be used in preference to the usual extension of the original wound with its extensive division of muscles. R. H. J. Swan [5] describes a similar procedure for ureterectomy in tuberculous kidney, and I have myself used it for a similar purpose with great satisfaction.

The advantage of the extraperitoneal incision of the ureter appears to me to be the very small amount of leakage which occurs even though accurate suture of the incision is impossible; as a matter of fact, I believe it is unnecessary in many cases to close the incision at all, and the absence of sutures makes the subsequent development of stricture less likely. If a calculus be arrested in the intramural portion of the ureter and cannot be dislodged by the ureteral catheter or operating cystoscope it should be removed by the transcystic operation.

Leeds.

THE PRIMARY CAUSE OF RHEUMATOID ARTHRITIS.*

BY H. WARREN CROWE, M.D. OXON.

IN a paper on the etiology of rheumatoid arthritis, published in THE LANCET last May,[1] I described an organism which I had isolated from the urine in a large proportion of cases of rheumatoid arthritis and neuritis, and a further paper complementary to this was published by Dr. A. B. Soltau in the same issue. Though similar in microscopic appearance to the pyogenic staphylococci, there were certain marked points of difference in culture, and of them, the most important for easy distinction was the appearance of the growth on a medium composed of eggs slightly tinted with neutral red. The organism was spoken of under the temporary descriptive name of the staphyloid coccus A. The pyogenic staphylococci produce rose-red colonies which turn to a vivid orange, whereas the colonies of the staphyloid coccus A remain rose-red or become gradually paler. Both produce indentation in the medium. These characteristics—colour and indentation—are diagnostic.

I left two questions open: the first, as to whether this organism was causal or merely casual in rheumatoid arthritis; the second, amongst what group of germs this staphyloid coccus A should properly be classified. This paper is a contribution towards the further elucidation of these two points. To deal with the latter first.

It was first suggested to me by Dr. J. Matthews, of St. Mary's Hospital Inoculation Department, that the germ very probably was one of those which inhabit the human skin, and which were named by Welch [2] the M. epidermidis. This turns out to be the case. The sugar reactions are the same: Broth culture turbid; pigment on agar white; acid and clot in milk; liquefies gelatin slowly; acid formation from action on maltose, lactose, but not mannite, glycerine usually, but not always. The growth on neutral red egg medium is identical and serum reactions are parallel. Fig. 8 shows a series of bloods tested for complement fixation with a typical staphyloid coccus A and a M. epidermidis albus isolated from a self-produced blister on the skin of a girl suffering from hysteria. The broad black bands in the tables indicate complete hæmolysis of sheep's corpuscles, partial hæmolysis being shown by a fainter colouration. These reactions are not exactly parallel, but I think sufficiently so to show that the organisms are closely related. Fig. 1 shows an opsonic curve determined in respect of both organisms. Four specimens of serum were examined—the first before a two-million dose of staphyloid stock vaccine was given, and the second, third, and fourth 12 hours, 24 hours, and 48 hours respectively after the injection. The curves are similar, though not identical. The only difference which I have found to exist between the particular cultures used for these experiments is that the staphyloid coccus A liquefies gelatin at a slower rate than the epidermidis albus.

In order to avoid the further use of such a clumsy expression as the staphyloid coccus A, I wish at once to give the germ what I suggest should be its correct biological title, but for this purpose one must anticipate slightly, and assume the proofs, which I shall immediately put forward, that this organism is the primary cause of rheumatoid arthritis. It would then be appropriate to denominate the microbe as the M. epidermidis, variety deformans, or perhaps, since that is somewhat unwieldy for common use, I may be permitted to allude to it in future under the shorter name of the M. deformans. I would like here to express my great appreciation of Professor R. T. Hewlett's kind assistance in helping me to decide on a proper title.

Permit me now to enter upon the justification of what must, I am certain, seem to be a very great assumption; and to clear the ground, under this term rheumatoid arthritis I would include only those forms of arthritis which present no demonstrable infection of the joints, and which conform more or less strictly to that typical primary polyarticular disease, sometimes called polyarthritis deformans, characterised by fusiform swelling and redness of the joints, frequently symmetrical in character, usually commencing in the fingers, and associated with glossiness of the skin and muscular degenerations and contractures. I expressly exclude rheumatic joints, and all cases of infective arthritis, such as arise as the result of the entry of the gonococcus, pneumococcus, and other germs into the joint itself.

Bacteriologists agree that serum reactions hold a

very important place in proving a causal connexion between a given disease and a given organism. Of these, the complement-fixation reaction is probably the most important. The first four tables give the results of sera tested by this method. The exact technique was as follows. An emulsion of a 24 hours' culture of the M. deformans was standardised and killed by heating at 60° C. for an hour. The sera of Fig. 4 were all freshly drawn and no complement was added. In the rest of the tables all serum was heated for 15 minutes at 60° C. to destroy complement, and then fresh complement in the form of normal human serum was added. Fleming's method was followed. Two volumes of serum, one being that under examination, the other fresh human serum (complement), were run into miniature test tubes, and four volumes of normal saline or the various dilutions of the standardised emulsion respectively added. The mixture was kept at blood heat for 20 minutes, when one volume of 5 per cent. (or in some cases 10 per cent.) washed sheep's corpuscles were stirred into each tube. A reading was taken after a further half to three-quarters of an hour at blood heat. The thick cross line is drawn at that point below which no control blood fails to show hæmolysis. With a view to avoiding all personal bias, Fleet-Surgeon Kilroy kindly performed some independent tests for me without knowledge of the sources of the majority of the sera, and in Figs. 4 and 7 his results are recorded. I must express my very deep sense of gratitude to him for his kind assistance, which was the more valuable on account of his extended experiments in the complement-fixation test, commonly known as the Wassermann reaction for syphilis.

In Fig. 4 it is seen that a very wide series of dilutions were examined. The first blood and the last three were controls from perfectly healthy individuals. The second serum was taken from an extreme case of rheumatoid arthritis; the third also from a case of frank rheumatoid arthritis; the fourth from a patient who had had rheumatic fever and suffered from chronic rheumatism, but had no symptoms whatever of rheumatoid arthritis or neuritis. In Fig. 5 the same emulsion was used, the first and fifth sera being controls. The middle three were each cases of rheumatoid arthritis. Fig. 6 shows some eight cases, in which the reaction was used for diagnosis where an early stage of rheumatoid arthritis was suspected, but the organism was not found in the urine at the first attempt. All suspects were positive with two exceptions; No. 12, in which the symptoms were confined to two joints, and these greatly enlarged by osteophytes. It was, in fact, a case of osteoarthritis, and not necessarily related in any way to rheumatoid arthritis. The opinion has been expressed that the cure of rheumatoid arthritis results in the formation of osteophytes producing a condition of osteoarthritis, but whether this be true, or whether, on the other hand, osteoarthritis and rheumatoid arthritis are different diseases, in either case a negative complement-fixation test was to be expected. The other exception, No. 9, was a very interesting and instructive case. Rheumatoid arthritis in typical form attacked a lad whilst in hospital. The test was performed three weeks after the disease appeared. The result was negative. A month later, however, on testing the blood again, a positive result was obtained (No. 19 of Fig. 7). After a further month, during which the patient had been treated by vaccines of this organism, and when the disease seemed to be fast disappearing, a further test was performed. The result was negative. Fig. 7, one of Fleet-Surgeon Kilroy's, is, I think, extremely convincing. He informs me that Serum No. 1 was taken from a case of acute Bright's disease, whose urine had yielded the M. deformans together with a streptococcus, and the blood was taken after he had regained his health. The result of the test was negative. Sera 2, 3, 4, 15 were normal men; 16, 17, 18, 19, all typical rheumatoid arthritis; 9, a convalescent pneumonia. It will be seen that all the rheumatoid patients gave positive results, and none of the others. Complement-fixation tests, then, afford conclusive evidence that the M. deformans is pathogenic in rheumatoid arthritis.

In the light of these tests, and with the addition of all cases seen up to September last, I am now able to revise the incidence table previously published.[3] Taking all positive tests to indicate that the organism is present and pathogenic, in 26 cases of typical rheumatoid arthritis the organism was present in all. It was cultured in 22 and positive complement-fixation was demonstrated in the remaining four. In a further 14 less severe and doubtful cases of rheumatoid arthritis, the organism occurred in 11, being cultured from 9. If neuritis is included, and for reasons which will shortly appear it seems that neuritis not improbably should be so included, the total number of cases becomes 48, and the incidence 45—that is to say, 93·75 per cent. Streptococci were present in addition to the M. deformans in 21 cases and B. coli in 7. It must not be supposed that the M. deformans never appears in the urine in any other conditions. I have found it in two or three cases of mild septicæmia, occasionally in neurasthenia, and also in rheumatism; among 35 of such cases recently investigated it has appeared 13 times.

I turn now to other serological evidence.

Agglutination tests.—These are not very satisfactory. Some cultures seem to give good tests; others not so. A strain with which I was working earlier gave fair agglutination; but my present ones fail to do so. Fig. 9 shows an agglutination series. Nos. 5 and 6 were control bloods; in Nos. 1 and 4 the M. deformans was present; Nos. 2 and 3 were cases of frank rheumatoid arthritis. The same sera were used as for complement-deviation test (Fig. 4). Again the evidence, such as it is, is favourable,

Opsonic data.—Figs. 2 and 3 show the opsonic response to a medium dose of a vaccine of the organism during a course of treatment. In both charts a typical immunity curve is developed. The patients suffered from typical rheumatoid arthritis. It is of interest, and, I think, of importance, to note that where a negative phase is seen as in these two charts it is almost invariably associated with increased swelling of the affected joints and marked rigidity. An experimental dose of M. deformans vaccine given to a normal person produced no fluctuation in the index. To use a legal phrase, this completes the evidence for the prosecution of the M. deformans. In order to summarise the facts here mentioned and bring them into line with others, some of which have

[3] THE LANCET, May 17th, 1913, p. 1377.

FIG. 1.

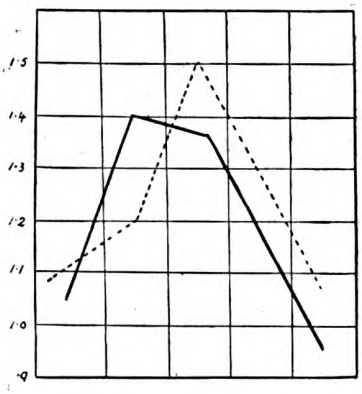

FIG. 2.

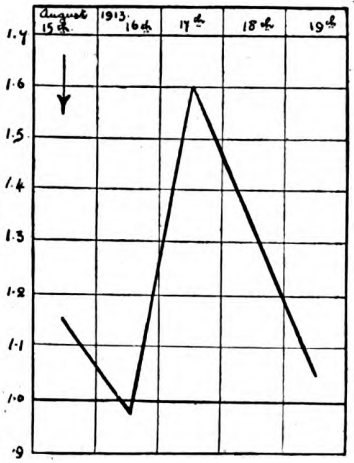

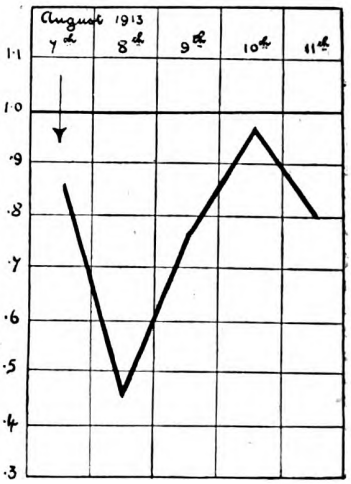

FIG. 3.

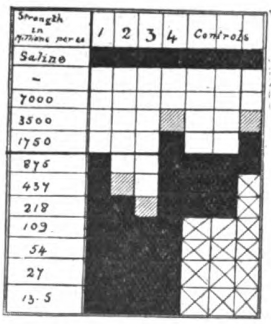
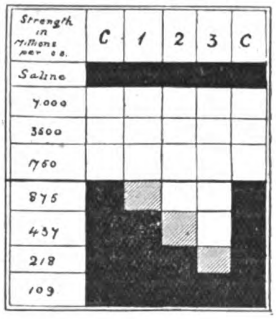
already been published elsewhere,[4] I may perhaps be permitted briefly to review the various points in their logical sequence.

Some three years ago, from the blood of a phthisical patient who suddenly developed acute arthritis of the left knee-joint associated with brachial neuritis, I isolated a diplococcus which I have since learnt to recognise as the organism here described—the M. deformans. The case was a remarkable one, for though by no means ill the patient (a young woman of 34) had had for certainly three years previously a raised temperature, which only on the rarest occasions dropped below 100° F. night or morning, and usually remained about 101°. Never had it been found to be normal, though two daily observations had been made during the whole

FIG. 4.





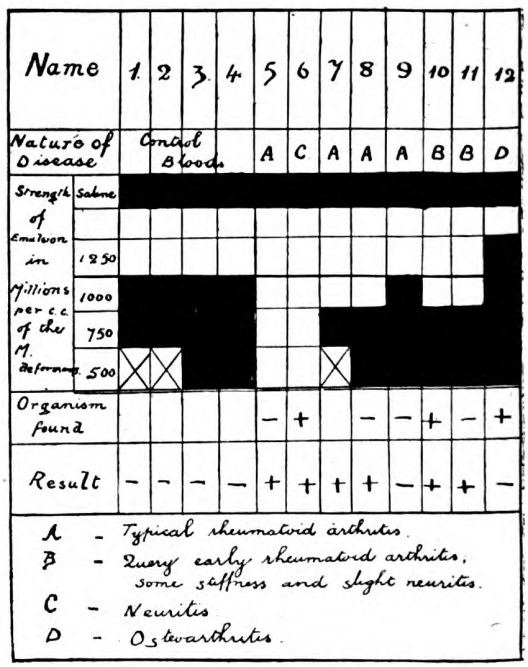


FIG. 5.

of the period. A vaccine prepared from this organism produced remarkable results, in that after a very few doses the knee-joint became well and again serviceable, the neuritis disappeared, and the temperature dropped to normal. It was impossible to avoid the conclusion that this diplococcus was causative of the arthritis, the neuritis, and the fever. A year later, within a week of each other, I had the catheterised urine sent me of two women, both suffering from acute rhematoid arthritis coming on shortly after parturition. The M. deformans was found in pure culture and in large numbers in both cases, and in both, vaccines of the organism produced that characteristic result, which one always associates with the injection of a vaccine prepared from the organism pathogenic in any given case. About the same time a male rheumatoid patient consulted me. He had a chronic nasal discharge, in which the M. deformans was found. Still more important, it was present in pure culture in the urine. Here, also, the effect of a vaccine was obvious. It was already impossible to dissociate rheumatoid arthritis from the M. deformans.

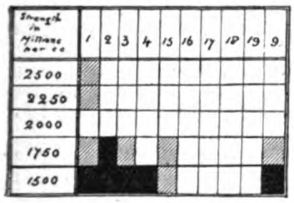
FIG. 6.

These four cases, then, which I have not hitherto described, provided me with the necessary starting-point for systematic investigation. Add now to this the further evidence I have adduced: incidence in the urine, 81·25 per cent., complement-fixation tests, these showing when combined a germ incidence of 93·75 per cent. in all cases of rheumatoid arthritis, obvious or suspected, opsonic data, and finally the clinical response to vaccines; and it becomes almost

[4] Ibid.

impossible to avoid the conclusion that the M. deformans is the actual primary cause of rheumatoid arthritis. I chose the urine as my *materies morbi*, because my conception of rheumatism proper, which is by no means to be confused with rheumatoid arthritis, was based on the fact that the causal streptococci are almost invariably to be found in the urine, without any manifest morbid process in the kidneys, or even urinary symptoms. Presumably rheumatic streptococci are circulating in the blood and excreted by the kidneys. These organisms, too, have been shown to be common inhabitants of the human digestive tract. Obviously these streptococci are not particularly virulent, for the bacteriuria is not associated with any illness

FIG. 7.



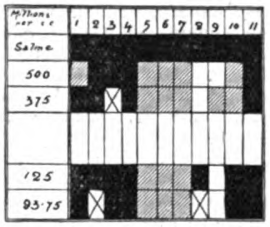


FIG. 8.

The upper dilutions in Fig. 8 are those of the staphylococcus A; the lower dilutions, M. epidermidis albus.

beyond chronic rheumatism. They would, however, possess potential virulence, for from acute rheumatic cases the same organisms have frequently been isolated from the blood, and rheumatic streptococci, whether isolated from the urine of chronic rheumatism or from the blood of acute rheumatic disease, produce the same condition of arthritis in rabbits. If rheumatism, then, is caused by organisms which originated as saprophytes from the bowel, it would seem that such a similar disease as rheumatoid arthritis might also be caused by some common saprophytic and avirulent organism. In both cases the germ would owe its continued existence to the fact of its avirulence; its very innocence would be its protection, and the immunity mechanism unstimulated by such comparatively harmless microbes, would fail to produce sufficient antibodies, or to wage effective war on the insidious invader. And so the germ would multiply and flourish exceedingly, but without much harm to its host, except when its numbers became excessive.

I have already shown that the M. deformans belongs to the M. epidermidis group. Thus rheumatism and rheumatoid arthritis present a parallel pathology, in that the former is caused by a common saprophyte of the bowel, the latter by a common saprophyte of the skin, which gains access to the blood, whence it is excreted or passively filtered through the kidneys, and thus comes to be discharged in the urine.

Apart from various rival germs, which have been described as having been isolated from the joints in certain forms of primary arthritis, confirmation of which is still lacking, there are four important criticisms which may be levelled against my hypothesis. The first is that streptococci, B. coli, and other organisms have been found in local foci of infection in cases of rheumatoid arthritis, and that treatment by vaccines of such organisms has been known not infrequently to cure the arthritis. It is this experience mainly which has given rise to the supposition that primary rheumatoid arthritis has not a definite single bacterial cause, but may be produced as the result of the activities of different germs. I do not propose to combat this by direct denial, nor do I anticipate shipwreck on the point. I merely put forward the suggestion that my hypothesis is by no means disproved because it may be shown that other mischievous germs are at work. I have frequently found them myself, and have been convinced of their pathogenicity. My claim is that these organisms constitute a mixed secondary infection. An analogy will place the matter in a clear light. Let us suppose that the tubercle bacillus had never been discovered. In the present state of bacteriology and vaccine therapeutics, what would be the inevitable conclusion? That the organisms found in the sputum were the cause of the condition: streptococci, B. influenzæ, M. catarrhalis, pneumococci; any of these alone, or in combination, would be supposed to be capable of causing phthisis, as we know it, and it is equally certain that some cases of phthisis treated by vaccines of these organisms would be reported as cured. This is exactly what has happened in the case of rheumatoid arthritis, and I submit that such evidence has really no bearing whatever on the hypothesis that there is a primary causal organism in this disease.

The second criticism might well be that this organism has not been found in the diseased joints. It is a more formidable objection. But since no organism of any kind has been found in the tissues of the affected joints, with the exception of some few cases, which do not seem to have a general application, and of which confirmation is lacking, this criticism would equally apply to any organism put forward as the cause of the disease. The

M. deformans, however, is so easily stained and recognised that there is little likelihood of its presence having been overlooked in the joint tissues, and the difficulty is very real. The following facts, however, indicate a possible explanation: (1) I submit that a very large proportion of cases of rheumatoid arthritis, if not all, are either preceded by or associated with neuritis; (2) the joint lesions have been considered to be trophic lesions; (3) the M. deformans occurs with remarkable frequency in the urine in cases of neuritis (of 8 cases it was present in all), and from the incidence

and from serum tests carried out on the same lines as above one is impelled to the conclusion that neuritis (excluding perhaps toxic forms) and rheumatoid arthritis are one and the same disease, both produced primarily by the organism which I have described, though frequently complicated by infections with other pathogenic germs; and (4) spinal lesions have frequently been described in cases of rheumatoid arthritis.[6] Further investigations are required, but they should be directed either towards searching for the M. deformans in some portion of the nervous system or towards demonstrating the presence of some nerve toxin produced by it. It will now be plain why I include neuritis in the incidence table.

Again, it may be objected that the M. deformans may play merely a similar rôle to the M. neoformans in cancer; that one is only dealing with a secondary infection, and that the primary cause is still to be sought. It is conceivable, but seems to me unnecessary, to invoke such complexity for the etiology of rheumatoid arthritis. Cancer differs in that the M. neoformans hypothesis is obviously insufficient by itself to explain the disease. Streptococci are, I think, accepted now as sufficient in themselves to produce rheumatism, and why not the M. deformans to produce rheumatoid arthritis?

Lastly, a plaint may be lodged that no animal experiments have been done. I regret it, but facilities have been lacking, and I thought it needless to defer my communication on that account. All the facts were remarkably favourable, so that they seemed sufficient in themselves to prove my hypothesis, and further, with the advent of serum reactions, than which no evidence can be more convincing, the necessity for fulfilling Koch's postulates in their entirety before assuming the microbial cause of a disease has somewhat diminished. On the first opportunity, however, the attempt will be made.

In conclusion, then, I would describe rheumatoid arthritis as a disease caused primarily by a common inhabitant of the skin, the micrococcus epidermidis, variety deformans, or more shortly, the micrococcus deformans, and I would further suggest that the germ produces the disorder mainly by its action on some portion of the nervous system, and lastly that other pathogenic germs are frequently actively engaged as a secondary mixed infection.

My best thanks are due to Fleet-Surgeon L. Kilroy and Professor Hewlett, whose assistance I have already acknowledged, and to all those medical men who have been instrumental in supplying me with material for this investigation, amongst whom I should like to mention more particularly Dr. A. B. Soltau, of Plymouth.

Yelverton, Devon.

Still (tenth edition, revised); "A Short Practice of Midwifery for Nurses," by Dr. Henry Jellett, master of the Rotunda Hospital, Dublin (fourth edition, revised); and "Lectures on Medicine to Nurses," by Dr. Herbert E. Cuff, late medical superintendent of the North-Eastern Fever Hospital, London (sixth edition).

A CASE OF TUMOUR OF THE PITUITARY BODY.

BY A. L. TAYLOR, B.Sc., M.B. EDIN., M.R.C.P. EDIN.,
ASSISTANT MEDICAL OFFICER, DERBY BOROUGH ASYLUM.

THERE are in the following case features which, I believe, justify its publication in the columns of THE LANCET.

The patient, a married woman, over 40 years of age, first came under observation in 1908 on account of mental symptoms. These at first consisted of apathy, with loss of memory and emotional reaction. An ophthalmoscopic examination at this time revealed nothing abnormal, and there was no complaint of headache or vomiting; the mental state would not allow of the fields of vision being tested. Frequent incontinence of urine and fæces was present, due probably to the mental indifference. In December, 1908, she was sent to the Derby County Asylum, and while there the mental apathy became more profound. In April, 1909, she was tried at home again, but did not improve, and had several fits indistinguishable from ordinary epileptic seizures. All this time she took her food well, but remained totally indifferent to everything else, being very somnolent and staying in bed all day. She was readmitted to the Derby County Asylum in October, 1911, and transferred to the Borough Asylum in December, 1911.

On admission here she was a woman aged 48, of middle height, dark complexion, and satisfactory general nutrition; the hands and feet were small and well formed. Physical examination revealed a mitral presystolic murmur, somewhat myotic pupils with a sluggish light reaction, dull flexor plantar reflexes, ordinary knee-jerks, and no diminution of the pain sense so far as could be made out. The urine beyond being rather concentrated showed no abnormal features. The mental condition was one of apathetic dementia with inability to answer any but the very simplest questions, and complete indifference to the passage of the evacuations; she complained of no pain; she resented greatly any attempt to examine her eyes, so that ophthalmoscopy was not possible, but she certainly suffered from marked dimness of vision, as evinced by her manner of eating and going about. This became more pronounced from month to month. On her admission there was no physical sign of paralysis or paresis, and she was able to walk quite well. Her mental symptoms became more accentuated, and in March and April she had two fits with bilateral convulsions. About this time weakness of the right hand showed itself, and she also had several mild attacks of painless vomiting. On June 1st, 1912, she was noticed to become even more drowsy than usual, and in the evening passed into a series of fits, 15 of which succeeded one another without return of consciousness. She remained comatose with very stertorous breathing, and died in the middle of the following day.

Necropsy.—On removing the calvarium, which was markedly increased in thickness and density, especially in the frontal region, the following evidence of extreme cerebral compression was noted: The dura was very tense, the subdural space practically obliterated, and the superficial convolutions perfectly flattened out. On removing the brain an ovoid tumour was seen in the centre of the anterior cranial fossa; it measured 4·5 cm. transversely and 6 cm. antero-posteriorly, was firmly attached to the sella turcica, and less so to the cribriform plate of the ethmoid. The surface was somewhat nodular and the consistence firm, the growth being quite circumscribed, and only exerting pressure on the adjacent parts. (See Fig. 1.) A deep hollow was thus present on the base of the brain extending from the posterior perforated spot to the frontal pole, and being widest midway between these two points. The floor of the hollow consisted of the flattened convolutions of the mesial and inferior surfaces of the frontal lobes, the optic chiasma and the olfactory tracts and lobes not being distinguishable. Sections of the hardened brain showed that the cavities of the lateral and third ventricles were almost absent; the brain was otherwise healthy to the naked eye, and weighed 41½ oz. The tumour was kindly examined by Dr. Ford Robertson, of the Scottish Asylums Laboratory, and proved to be an ordinary spindle-celled sarcoma. (Fig. 2.)

One of the most interesting features of the case is the pressure on the frontal lobes producing very definite and discrete mental symptoms—i.e., gradually increasing apathy and emotional atrophy, ending in profound stupor or dementia. This fact

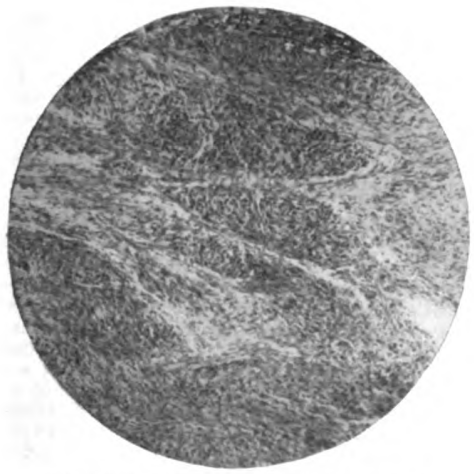

FIG. 1.

Photograph of floor of cranium showing tumour of pituitary body.

agrees with the current theory that the frontal cortex is the seat of the higher intellectual and emotional processes. One finds a record of a very similar case [1] in which there were no fits, the only

FIG. 2.

Microphotograph of sarcoma of pituitary body.

symptoms being amaurosis and progressive intellectual impairment. A case of sarcoma of the infundibulum [2] of a much more malignant nature than the above occurred in this asylum three years ago; there were epileptic fits, and the mental state was acute excitement followed by stupor. The presence or absence of fits in these cases may only be a matter of individual susceptibility. The three cases mentioned are excellent examples of tumours growing from the pituitary without any dystrophic symptoms.

I should like to thank Dr. G. Bruce, of Melbourne, Derbyshire, for information as to the early history, Dr. W. Ford Robertson for his kind assistance, and Dr. S. R. Macphail, medical superintendent of the Derby Borough Asylum, for permission to publish the case.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Clinical Cases.—The Treatment of Syphilis.

A MEETING of this section was held on Nov. 14th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. A. M. GOSSAGE showed a case of Subcutaneous Granulomata. The patient was a girl, aged 3½, who was admitted into hospital on August 12th last for stiffness in the left knee and pain and stiffness in the left wrist. At the age of 2 her mother noticed that the left knee was held stiff and slightly bent so as to make her walk awkwardly. Lately this had been worse, and the child frequently wanted to rest. Three days before admission the left hand was noticed to be doubled up, and she complained of pain in her wrist. No lumps had been noticed in the trunk or head. On admission she was found to be a healthy-looking child. The left wrist was flexed and the dorsum of the left hand was somewhat swollen; anteriorly over the tendons at the wrist there was some reddish discolouration, and there was some thickening under the skin. The child was unable voluntarily to extend the hand and fingers, whilst forcible extension caused pain. There were about 20 subcutaneous nodules, from the size of a millet seed up to a small pea, under the skin of the scalp, neck, and trunk. These were not tender or painful, and the skin moved over them freely, but in some places was slightly discoloured. Those over the scapula moved with the movements of the arm. The swelling in front of the wrist seemed composed of several nodules matted together, but there was also some swelling of the skin itself, and the tendons were involved in the mass. The left knee was apparently normal, and no other abnormality could be found elsewhere. In the night of August 29th there appeared pain and swelling in front of the right wrist, with flexion of the wrist and some swelling in the dorsum of the hand. On examination a precisely similar condition was found to that in the left wrist—i.e., some thickening and discolouration of the skin, and subcutaneous swelling, which appeared to be formed of several nodules matted together, with involvement of the subjacent tendons. On Sept. 16th it was noticed that the right knee was sometimes drawn up, and that the child seemed unable to straighten the leg again, but forcible replacement by the nurse caused no pain, and the knee subsequently seemed normal, and there was no swelling. There was no alteration in the condition until Oct. 3rd, when she was ordered iodide of potassium, 3 grs. three times a day. Since then the tumours had got smaller and many had disappeared, whilst the swelling in front of the wrists had diminished, and the movements of the hands and wrists had become painless and more free. On Sept. 9th two of the tumours were cut out, and were subsequently examined by Dr. R G. Hebb, who reported as follows. Both tumours were surrounded by a zone of connective tissue in which were reticular histological tubercles with numerous large giant cells. The central areas were filled with some homogeneous substance which was crowded with small cells of irregular shape; also certain bodies somewhat resembling in appearance Charcot-Levden crystals were demonstrable by the Ziehl-Neelsen method. The nature of the growth was uncertain. No organisms were

discovered. The tumours having been put directly into formalin, no culture could be made from them. The Wassermann and von Pirquet reactions were both negative. Dr. Gossage said that the three probable causes for granulomata of this type were (1) syphilis, (2) tubercle, and (3) sporotrichosis. There was nothing in the family or personal history to suggest syphilis, and with a negative Wassermann reaction this might be excluded. The histological appearances, the rapid improvement with iodide of potassium, and the negative von Pirquet reaction similarly weighed against the diagnosis of tubercle. In the absence of a culture of the organism one could not be certain of the diagnosis of sporotrichosis, but this seemed to be that which was most probably correct. It was to be noticed that there was no tendency for the tumours to break down in the two months before treatment with iodide was commenced.

Mr. W. J. MIDELTON showed two cases of Arthritis Deformans treated by continuous counter-irritation. The first patient was an elderly woman. Sixteen years ago she first noticed rheumatic symptoms; the joints of the fingers, knees, and ankles eventually became markedly swollen up to two years ago in spite of treatment. Severe attacks of sciatica occurred at times. The patient was first seen by Mr. Midelton with a view to treatment two years ago. At that time she was very depressed and in much pain. Salicylates relieved the latter somewhat, but increased the depression. On examination the patient was found to be too thin; all the phalangeal joints were swollen and of the rheumatoid type. The fingers were cyanosed. The knees and ankles showed enlargement of a soft character with little or no bony change. There were soft pads beneath the ligamenta patellæ bulging on each side. The legs were slightly œdematous. There was a fibrous nodule at the back of the proximal phalanx of the left thumb of about the size of a small hazel-nut and very hard. The subcutaneous tissue of the legs was thickened and suggestive of myxœdema. The toes were cyanosed and the nails withered very much, having practically disappeared in several instances. Very few teeth remained; the patient had obviously suffered for many years from pyorrhœa alveolaris, and the teeth had in most instances become so loose as to need extraction. No marked affection of the heart or lungs was found, but the stomach and bowels were thought to be atonic. Treatment by means of continuous counter-irritation was commenced on Sept. 27th, 1911. On Oct. 31st the swelling was gone from the fingers and the tenderness from the feet. Eventually the patient became so well and active that she undertook strenuous work—on her feet all day and out socially at night. She had had slight recurrences from time to time, but the treatment always readily subdued them, and the patient remained well and active. The pads had gone from beneath the patellar ligaments and the nodule from the thumb. She was wearing shoes that had been put aside for years. Her attacks of sciatica were now slight. The toe-nails had grown again. Excessive fatigue contributed more to recurrences than anything. The second patient was a middle-aged woman. Five years ago the ankles swelled; at about the same time she had a "paralytic seizure," the right arm and the left leg and the back of the neck being affected. There was difficulty in moving the head, and much pain. Her walking power gradually returned, but was variable. She suffered from syncopal attacks, with at times actual loss of consciousness lasting two hours. The attacks had increased in severity. All the joints were more or less tender and stiff, but not much swollen. There was loss of muscular power in the knees, their flexion and extension being limited. The right elbow and neck were very tender. A typical rheumatoid condition of the first and second metacarpo-phalangeal joints was present. The skin of four fingers was glossy. The wrists were puffy, but moved fairly well. She was scarcely able to move the head at all, the features being mask-like. The right arm was practically useless. Many of her teeth were out and the remainder were infected at the roots. Treatment by continuous counter-irritation was commenced in February, 1912. The patient had not been out of the house for four months when first seen, and a very gloomy prognosis had been given. The heart had been thought to be in an advanced state of fatty degeneration. Within a very short time after the commencement of treatment by means of counter-irritation the patient greatly improved. She regained power to write, to sew, and to walk up and down stairs easily. The patient had become increasingly active and had practically ceased to have any syncopal attacks; she still had treatment from time to time.

Dr. F. PARKES WEBER showed a case of Rheumatic Nodules associated with Rheumatic Torticollis. The patient, aged 11, was a pale, rather delicate-looking boy, with a certain degree of wry-neck, the neck being bent towards the patient's right with the chin turned a little to the left. There was no arthritis, nor did the boy complain of any pain or tenderness anywhere, but there was some puffiness about the second and third metacarpo-phalangeal joints in both hands, and over these joints very small rheumatic nodules could be seen and felt. There were moderate-sized rheumatic nodules over both elbows and both knees, those over the knees being the largest and the most numerous. The olecranon bursa at both elbows was enlarged. The heart was excitable in action, and the impurity of the first sound at the apex suggested slight endocardial changes at the mitral valve. In the absence of fever the frequency as well as the excitability of the heart's action suggested slight myocardial implication. There was a variable systolic murmur to be heard over the "pulmonary area." Some of the lymphatic glands in the neck were a little enlarged. The history was that the boy enjoyed good health until the present illness commenced on Sept. 13th, 1913, with pain in the left ankle; this joint became swollen on the following day. He was treated by rest in bed and small doses of salicylates. At first there was fever up to between 102° and 103° F. This left him on Sept. 20th, but after the 24th to the middle of October there were occasional evening rises of temperature to about 100°. Since then there had been no fever. The wry-neck appeared at the end of September, and was at first accompanied by a little pain at the lower posterior part of the right side of the neck. The rheumatic nodules were first noticed in the middle of October, at first only on the elbows and knees, later over the hands also. Recently he had been treated with subcutaneous injections of rheumatism phylacogen and with careful massage of the neck. Roentgen ray examination showed no bony change in the neck. The special interest of the present case was the association of the wry-neck with rheumatic nodules and affection of the olecranon bursæ, suggesting that a kind of true "*rheumatic* fibrositis," analogous to that which produced rheumatic nodules over the periosteum and fibrous structures, was the cause of the wry-neck.

Dr. PARKES WEBER also showed a case of Angiokeratoma with Bony Changes. The patient, aged 16, was a physically rather under-grown and under-developed boy, mentally quite normal. His extremities were inclined to be cyanosed, and in winter, since the age of 4, he had suffered severely from chilblains of the hands and feet and ears, which had left a good deal of scarring. Owing to these cicatricial changes the movement in some of the terminal finger-joints and in the toes had become very limited. On the hands were a number of dirty-reddish spots, which were minute warts on angiomatous (telangiectatic) bases; they added a peculiar speckled appearance to the cicatrisation resulting from the chilblains. On the feet, in addition to the scarring of the toes from chilblains, there were a number of large, hard "corns" (keratomata); some of these resembled the callosities which occasionally preceded perforating ulcers. In the Rœntgen ray skiagrams of the hands and feet the terminal phalanges of the hands appeared somewhat stunted, and there was slight general rarefaction of all the hand bones; in the feet there was marked deformity of the terminal phalanges, and there was more rarefaction of the bones than in the hands; the distal portion of the terminal phalanx of the left big toe had disappeared, as if by a process of absorption, like that sometimes seen in Raynaud's disease. In spite, however, of the tendency to cyanosis of the extremities the patient had never had any definite attacks of Raynaud's phenomena. The knee-jerks were exaggerated, but there were no signs of syringomyelia or other organic nervous diseases. Nor was there evidence of disease of any of the abdominal or thoracic viscera. The chilblain-like condition ordinarily associated with angiokeratoma of the hands and feet seemed to him insufficient in the present case to account for the bony changes revealed by Roentgen ray examination, and yet there had been no definite attacks of Raynaud's phenomena nor local tuberculous disease to account for them.

Dr. W. ESSEX WYNTER showed a case of Hæmophilia. The

patient, a man aged 22, was admitted to hospital in November, 1913, for hæmaturia. There were four sons, of whom the patient was the youngest, and no daughters. The eldest and second were both alive and well. The third died at the age of 15; he was a bleeder; the patient remembered his once cutting his thumb, which bled for days and led to his being admitted to hospital; he also had, occasionally, swelling of the joints which lasted some weeks. The patient himself, before he was aged 8, partly remembered and had been told that he had frequently painful swellings in the knees which necessitated his staying in bed, but always cleared up eventually. When aged 9 the patient had an attack of hæmaturia, unaccompanied by pain, which kept him in bed 14 days. At the age of 16 he sprained his right elbow-joint slightly; great swelling ensued, associated with pain and limitation of movement lasting 14 days. Frequent similar attacks had occurred since, affecting the elbows, the knees, and the right shoulder. The attacks occurred particularly in the autumn. Two years ago, after the extraction of a tooth, bleeding continued for 14 days. He was admitted to hospital for three days and oozing continued after his discharge. These were specific instances amongst many similar attacks of joint swelling and hæmaturia. The present attack of hæmaturia commenced ten days before admission with slight colouration, which gradually became more intense. The following day there was an attack of pain shooting down to the groin on the right side and lasting half an hour. Swelling of the right elbow commenced a week before admission accompanied by stiffness and some redness, a similar attack having occurred a month previously. When shown the patient was a healthy looking youth with bright complexion and was well nourished. There were some swelling and limitation of movement in the right elbow and ecchymosis of the skin in the outer and flexor aspect. The urine was almost porter-coloured and opaque, specific gravity 1020, acid, and contained albumin corresponding with the blood. Corpuscles were present in quantity. An X ray examination disclosed no stone nor any enlargement of the kidneys. The organs appeared to be quite normal, and apart from the hæmorrhage there was no sign or feeling of illness.

Dr. J. H. DRYSDALE and Mr. G. E. GASK showed a case of Splenic Anæmia; Splenectomy; Hæmatemesis 18 Months after the Operation. The patient, a boy aged 16, was admitted to hospital in December, 1911, for hæmatemesis and enlargement of the spleen. Two years before admission he first noticed a large lump in the left side of the abdomen. Since then he had gradually become paler and had been subject to attacks of giddiness. Four months and again two months before admission he vomited a large amount of blood. On admission the spleen was found to be much enlarged. Red cells, 3,525,000; hæmoglobin, 45 per cent.; colour index, 0·64; poikilocytosis; polychromatophilia present; white cells, 3000; all forms diminished in numbers; a few myelocytes. Wassermann's reaction was negative. In January, 1912, the spleen was excised by Mr. Gask, along with two or three spleniculi. In March: Red cells, 3,900,000; hæmoglobin, 54 per cent.; colour index, 0·7; white cells, 6400; polymorphonuclears, 2816; lymphocytes, 2816; large mononuclears, 678; eosinophiles, 38; and basophiles, 114 per cubic millimetre. He remained in good health till July of this year, when he vomited more than a pint of blood and fainted. He slowly recovered, and in September, after a short fit of coughing, brought up a thick silk ligature. He was readmitted in October. His blood count now was: red cells, 5,400,000; hæmoglobin, 90 per cent.; colour index, 0·83; white cells, 6600; polymorphonuclears, 2574; lymphocytes, 3630; large mononuclears, 99; eosinophiles, 198; and basophiles, 99 per cubic millimetre; no nucleated reds or myelocytes were seen. The red cells showed excessive variations in size and depth of staining reaction. Poikilocytes were numerous; reticulate cells, 1·8 per cent.; fragility: hæmolysis began between 0·45 and 0·4 and was not complete before 0·3. The interest of the case lay in the recurrence of the hæmatemesis 18 months after the removal of the spleen. Patients with splenic anæmia might live for 20 or 30 years without surgical interference, and they died sometimes as the result of operation. If they were to remain liable to attacks of hæmatemesis—which was, after all, their most dangerous symptom after splenectomy had been performed—it raised the question as to how far the operation was advisable. This patient was not cured of his disease, for apart from the attack of hæmatemesis he still had a leucopenia, his polymorphonuclears were only half the proper number, and many of his red cells showed abnormalities. His general condition was certainly improved, but one was precluded from saying that his life was safe from the dangers of splenic anæmia.

Dr. ARTHUR F. HERTZ and Mr. D. W. JOHNSON showed a case of Cervical Rib with marked vascular symptoms in a woman aged 45, and a case of Myatonia Congenita in a boy aged 3½ years.

Mr. C. A. BALLANCE showed a woman, aged 20, whose Facial Paralysis had been treated by facio-hypoglossal anastomosis (end to end) and end-to-end anastomosis of the descendens noni to the hypoglossal.

Mr. W. H. BATTLE showed a case of Microglossia in a child aged 1 year and 5 months.

Dr. ALBERT WILSON read a short paper on the Treatment of Syphilis by Arsacetin and by Excision of the Primary Sore.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Relation of Internal Secretions to Female Characteristics and Functions in Health and Disease.

A MEETING of this section was held on Nov. 6th, Dr. W. S. A. GRIFFITH, the President, being in the chair.

A special discussion took place on the Relation of the Internal Secretions to the Female Characteristics and Functions in Health and Disease. The paper introducing it, by Dr. W. BLAIR BELL, was distributed beforehand.[1] Allusion was first made to the great advances which have been made during recent years in the science of gynæcology and obstetrics. After pointing out that from a broad standpoint femininity itself is entirely dependent on the internal secretions acting in correlation,[2] Dr. Bell considered the more purely morphological and physiological aspects of the subject. The production of the female characteristics—primary and secondary—was traced to the internal secretions, and facts were quoted in support of the statement made. It was shown, too, how the internal secretions directly and through the general metabolism initiated the genital functions at puberty. By way of illustration the calcium metabolism was described in its bearing on the question under discussion. Next, the maintenance of the female characteristics and functions was dealt with, and experimental evidence was given of the importance of all the internal secretions in effecting this end. The conclusions in regard to the morphological and physiological aspects of the subject were: (1) The development and integrity of the genital organs and their functions are dependent on all the internal secretions, individually or collectively; (2) the removal of any one organ of internal secretion produces changes in the others, and by this means we gain some insight into the existing correlations; and (3) the general metabolism is altered by extirpation of any of these organs; this alteration in the general metabolism affects the genital metabolism. From physiological and morphological investigations the following information has been obtained which may be employed in the solution of clinical problems:—1. Our knowledge of the influence of the internal secretions on the sex characteristics and on the development of the genitalia helps us to understand the pathology of hitherto obscure conditions connected with sex characteristics and the development of the reproductive organs. So, also, can we trace the influence of the internal secretions on the psychology of our patients, for in women femininity is associated with psychical qualities which need not be defined here. These qualities are due to the combined action on the brain cells of the metabolic conditions produced by the feminine organs of internal secretion; and the normal psychical condition is frequently disturbed by pathological conditions of the endocrinous glands. 2. Since we know something of the influence of the internal secretions on normal menstruation we can note the abnormal effects produced in regard to the menstrual function, and conversely we can observe the effects produced on the organs of internal secretion by local derangements of the genital organs. 3. Knowing, also, the part played by the internal

[1] This will be published in full in the Proceedings of the Royal Society of Medicine.

[2] THE LANCET, April 15th, 1913, p. 944.

secretions in the metabolism of pregnancy, we can, in the same way, observe the effects of deviation from the normal. The second part of the introductory paper dealt with pathological and therapeutical considerations. First, derangements in the development of the genital organs and their functions were discussed under the following headings: (1) Imperfect and irregular primary development of the genitalia; and (2) irregular secondary development of the female genitalia and functions. It was shown under the first heading how pseudo-hermaphroditism might be produced, especially by hyperplasia of the suprarenal cortex. And under the second heading it was demonstrated how the onset of puberty (precocious or delayed) was under the influence of the organs of internal secretion. Next, derangements of the fully established female characteristics and functions were discussed. This part of the subject was dealt with at some length, since it was of considerable interest from a clinical point of view. The derangements of the fully developed sexual characteristics first came under notice. Then the derangements of the fully established functions were considered from the points of view of increased and decreased secretion from each special organ. Many clinical phenomena in connexion with menstruation and pregnancy were discussed in detail. The results of experimental investigations of the metabolism of animals after partial or complete removal of the different ductless glands were demonstrated by means of tables; and a series of photo-micrographs were shown to illustrate the structural effects produced on the other organs of internal secretion after the partial or complete removal of one of the members of the endocrinous system.

Dr. LOUISE MCILROY, who had been specially invited to continue the discussion,[3] considered the subject under the following headings:—1. The importance of comparisons between the results of experimental work upon laboratory animals and clinical observations—examples. 2. The influence of the internal secretory organs upon development. 3. The constituents of the ovary and their function. 4. The necessity for clinical records upon the effects of oöphorectomy before puberty, during reproductive life, and during pregnancy. 5. The effects of oöphorectomy alone as compared with oöphorectory combined with complete hysterectomy; influence of uterine secretion. 6. The clinical aspect of ovarian transplantation. 7. The influence of ovarian secretion upon metabolism, lactation, and the other internal secretory organs. 8. The influence of the internal secretory organs upon disorders of menstruation, with special reference to precocious menstruation, menorrhagia of puberty, and early menopause. 9. The treatment of gynæcological conditions by glandular extracts—examples. 10. The relationship between general toxæmias and derangements of the internal secretory organs. Dr. McIlroy thought it a happy augury for future work that there should be so much collaboration between the laboratory worker and the clinician. Much confusion as to the function of the ductless glands arose from want of proper comparison of the variations in different species of animals and of the human individual. The secretory organs modified sex development, but did not cause the assumption of secondary characteristics, as these will probably be found to be due to cell development in very early embryonic life. The effects of oöphorectomy alone as compared with combined hysterectomy were mentioned, and the influence of the uterine mucosa discussed; the clinical aspect of ovarian transplantation, the influence of ovarian secretion upon metabolism, and upon menstruation in correlation with the other internal secretory organs were brought forward. Treatment of menopausal symptoms by ovarian and mammary extracts, and menorrhagia by pituitary extract by the mouth gave encouraging results. The influence of the thyroid gland upon toxic conditions was a subject of great importance in gynæcological and obstetric conditions.

The two papers led to a very interesting discussion, in which many invited speakers took part. Among those who spoke were the PRESIDENT, Professor F. H. A. MARSHALL, Dr. T. R. ELLIOTT, Mr. JAMES BERRY, Dr. LEONARD WILLIAMS, Dr. R. MURRAY LESLIE, Dr. FLORENCE A. STONEY, Dr. AMAND ROUTH, and Dr. H. R. HARROWER.

Dr. BLAIR BELL replied.

[3] This paper also will be published in full in the Proceedings of the Royal Society of Medicine.

SECTION OF ANÆSTHETICS.

Tachycardia during Anæsthesia.—Paroxysmal Tachycardia.—Anoci-Association.

A MEETING of this section was held on Nov. 7th, Dr. J. BLUMFELD, the President, being in the chair.

Dr. A. L. FLEMMING gave particulars of a case of extraordinary Tachycardia during Anæsthesia. The patient was a healthy girl, aged 12, undergoing radical cure for hernia. Her heart was normal. The pulse-rate, noted before operation, was 84. No alkaloids had been given previously. Anæsthesia was normally induced with open ether. Five minutes later, after operation had been commenced but before any traction had been made on the sac, the pulse-rate was noticed to have increased to 274. The patient was apparently well; anæsthesia was moderate, and there was no cyanosis. Later the pulse-rate was 288. A change was made to chloroform and then back to ether without any alteration of the pulse-rate. The operation lasted about 30 minutes. Ten minutes after the operation there was some retching, the pulse-rate being 264. The patient was then turned on to her left side, when the pulse almost immediately dropped to 84.

Dr. W. BEZLY THORNE related the occurrence of Paroxysmal Tachycardia, lasting from four to six seconds, intermitting with a pulse-rate of 80, in a case of strangulated hernia in a patient suffering with aortic regurgitation and aneurysm of the common carotid artery. Preliminary doses of morphia and atropine were given; infiltration of novocaine and adrenalin, followed by chloroform at the operation. The tachycardia occurred the day after operation. Dr. Thorne also mentioned a case of tachycardia in which pressure over the præcordium had given relief.

A paper by Mr. J. H. CHALDECOTT was read (in his absence) by Mr. BRYAN on Some Impressions of Anoci-Association. He briefly described Dr. Crile's method [1]—viz., the hypodermic administration of morphia, atropine, and scopolamine previous to the operation; the employment of nitrous oxide and oxygen as a general anæsthetic; and, lastly, blocking of nerve channels by infiltration of the tissues with solutions of novocaine, urea, and quinine. He pointed out that the nitrous oxide was only used to keep the patient unconscious, and that for surgical anæsthesia one had to rely on the infiltration, any insufficiency of which would not be masked by the nitrous oxide. The chief difficulties of administration were in the early stages, especially if the patient had to be moved or lifted, and also during rough manipulations, and from the presence of gauze packings, &c., of the abdomen. Hewitt's apparatus was used; no rebreathing was permitted. With an experience of 60 cases his results had been very encouraging, unpleasant after-effects being insignificant, except in a few cases. He thought that a good trial of the method would prove it of great value, especially in bad cases.

Mr. C. W. G. BRYAN read a communication on Some Points in the Technique of Anoci-Association (Crile). The injection of local analgesics, he said, was to overcome the evils of shock, cyanosis, and rigidity under nitrous oxide and oxygen. He agreed with Crile that success largely depended upon the local injections and not upon increasing the depth of anæsthesia. Deep general anæsthesia merely masked the trauma inflicted on the patient's nervous system, and with this method painful manipulations were at once made manifest by cyanosis and rigidity. The injection should be made rapidly with pressure, into the various layers, before incision. Abdominal wall infiltration was sufficient where there was not much dragging on viscera. For complicated and deeper manipulations, retroperitoneal and mesenteric infiltrations would be necessary. Difficulty from cyanosis and rigidity was experienced in gastro-enterostomies and operations in the left upper part of the abdomen. Probably injections in the region of the cœliac axis would block sensations from most of the abdominal viscera.—A discussion followed in which the PRESIDENT, Dr. MAY DICKINSON BERRY, Mr. C. CARTER BRAINE, and others took part.

Mr. R. E. APPERLY gave a demonstration of a new Ether Junker Inhaler for nose and throat work.

SECTION OF LARYNGOLOGY.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Nov. 7th, Dr. D. R. PATERSON, the President (introduced by Mr. HERBERT TILLEY, the retiring President), being in the chair.

The PRESIDENT exhibited the following: (1) A Piece of Button removed from the Left Bronchus; (2) A Piece of Mutton Bone impacted in the Right Bronchus; and (3) A Feather, six inches long, removed from the Trachea and Right Bronchus.—The discussion was chiefly confined to the variations in symptoms produced by foreign bodies in the air passages and to methods adopted for their removal, and was taken part in by Mr. F. H. WESTMACOTT, Dr. G. W. HILL, Dr. W. JOBSON HORNE, Mr. C. W. HOPE, Dr. H. J. DAVIS, Mr. H. LAMBERT LACK, Mr. W. G. HOWARTH, Dr. J. DONELAN, and Sir STCLAIR THOMSON, the last named remarking that the mortality from foreign bodies in the air passages, which was formerly as high as 60 per cent., had dropped to about 1 to 3 per cent. since the introduction of the improved methods of treatment.

Mr. TILLEY: The removal of a Green-pea from the Right Bronchus by an improvised method.

Dr. P. WATSON-WILLIAMS read notes of a case of Cerebro-spinal Rhinorrhœa, with subsequent Sinusitis; operation; death.

Dr. DAN MCKENZIE: Endothelioma of the Ethmoid, which showed no sign of recurrence six months after removal by operation.

Mr. W. M. MOLLISON: A case of Epithelioma of the Floor of the Mouth and Tongue, and Ulceration of Soft Palate.—Mr. TILLEY drew attention to the tendency of chronic ulceration of the mouth becoming malignant.—Mr. P. R. W. DE SANTI, Mr. W. D. HARMER, and Mr. H. CLAYTON FOX also discussed the case.

Mr. PHILIP TURNER and Mr. MOLLISON: A case of Pneumococcal Infection of the Mouth and Pharynx.—Mr. TURNER remarked on the great improvement of the case without the aid of vaccine treatment.

Mr. THOMAS GUTHRIE: Tumour of the Palate (microscopical specimen).—The PRESIDENT remarked on the similarity between the structure of the specimen and that of the mucous glands found in the palate of the rat.

Dr. DONELAN: A case of Double Paralysis of the Superior Laryngeal Nerves of a patient in the course of disseminated sclerosis from lead poisoning.

Mr. T. B. LAYTON: (1) Fixed Crico-arytenoid Joint; phthisis; healed tertiary syphilis; and (2) Mass attached to the Laryngeal Wall.—The PRESIDENT suggested that this was due to prolapse of the ventricle.

Mr. LAYTON also showed a Tumour of the Right Vocal Cord.—Varying opinions were expressed as to whether the case was one of pachydermia or fibroma laryngis.

Mr. WESTMACOTT: 1. New pattern Knife and Cartilage Scissors with Specimens removed by them from cases of deviated septa. 2. Specimens from successive cases of Tonsils enucleated by Matthieu's guillotine. 3. Flexible Rubber Finger Guard.

Mr. H. A. KISCH: The Rhinomanometer.—The PRESIDENT remarked on the difficulty of maintaining the nasal cavities undisturbed during the use of this kind of instrument.

Dr. DAVIS: 1. A case of Minute Growth (? fibroma) on the Left Vocal Cord. 2. Skiagram of a Farthing in the Œsophagus of a Baby aged 2 years. 3. Fixation of the Right Vocal Cord, producing no symptoms, in a man aged 61. 4. Skiagram of a Face showing Arrested Development of the Lower Jaw.

Dr. J. DUNDAS GRANT: A case of small Tuberculous Ulcer localised at the anterior part of the left aryepiglottic fold.

Mr. HARMER: Perforation of the Septum Nasi causing Inspiratory Whistle.

Mr. DE SANTI: Case of Epithelioma of the Epiglottis with malignant glands in the neck after operation in March, 1913.

Mr. J. H. CONNOLLY: A boy, aged 5 years, with a large Pulsating Vessel in the right portion of the Posterior Pharyngeal Wall.

MEDICAL SOCIETY OF LONDON.

The Treatment of Neurasthenia.

A MEETING of this society was held on Nov. 10th, Sir DAVID FERRIER, the President, being in the chair.

Dr. J. S. RISIEN RUSSELL opened a discussion on the Treatment of Neurasthenia. His paper will be found in full on p. 1453 of this issue.

Dr. JAMES TAYLOR said that before endeavouring to deal with the subject of the treatment of neurasthenia he would like to state the conception which he had of this as a disease. The name was so convenient that he at least was, he knew, sometimes inclined to pigeon-hole under it a good many cases which perhaps did not properly belong there. So he had endeavoured to classify for his own satisfaction the cases which, in his opinion, were properly regarded as really neurasthenic. He had been forced, as the result of experience, to the conclusion that they had frequently to deal with a neurasthenic temperament—not really a disease. He thought they were all familiar with the temperament. It was characterised by over-anxiety and apprehensiveness as to any action contemplated, or the effects of it when performed. The subjects of it were very introspective, and what one might call their "mental refraction" was quite erroneous. They were often extremely ignorant of the simplest physiological facts, and had all kinds of curious notions as to the functions and arrangements of the internal organs. In many instances they were sexually vicious, but he could not satisfy himself that this was an inevitable accompaniment of the neurasthenic temperament. Those in the room who were students in Edinburgh 25 years ago or more would remember how often in the medical wards there were, as patients, men from the Orkney and Shetland Isles. They were usually physically sound, of characteristic Norse appearance, yet acutely miserable in a negative kind of way, and in spite of their profound religiousness "without God and without hope in the world." They had no energy, they were full of vague discomforts, and they imagined all kinds of visceral anomalies—that food did them no good because it remained for days in the stomach, that it did not nourish them because it passed unchanged, and so on. These patients did not develop any real mental disease, and they usually left the hospital in the same state in which they came. He had only seen one hospital case of this "morbus orcadensis" in London, actually from the remote islands. All these were characteristic cases of what he would venture to call the neurasthenic temperament. No doubt the cases usually seen of this temperament were more sophisticated. They had a greater command of words, but he ventured to think that their description of their condition, although more articulate, was not less vague. He had been much interested to learn from American text-books that in America the immigrant Scandinavian was regarded as more prone to neurasthenia than most. As to treatment in this condition, he believed it was almost always inefficacious, although a few symptoms might be relieved. As to what he would venture to call induced neurasthenia he was inclined to think that in the vast majority of cases it was the result of hard physical strain, combined with anxiety or unsympathetic environment or uncongenial work. Notorious examples were that of a devoted daughter of a poor physique nursing her mother whom illness had made querulous and exacting; a man of too fine fibre for the rough and tumble and insincerity of politics whose conscientious attendance at dull and unsatisfactory debates had broken down his physical resistance; the over-worked doctor whom anxieties and worries about patients, and perhaps some personal difficulties about money matters, had exhausted in regard to his physical stamina and deprived of sufficient sleep and recreation. Even worse was the clergyman, often young, whose emotional temperament had been tried by the various demands upon it, and whose reason had been more or less outraged by the attempt to swallow dogmas which no reasonable man could digest. *Apropos* of this he thought it was almost worth quoting a remark of one who was not only a literary man but also a doctor, Oliver Wendell Holmes:—

Stupidity often saves a man from going mad. We frequently see persons in insane hospitals who went there in consequence of what are called religious mental disturbances. I confess that I think better of

them than of many who hold the same notions, and keep their wits and appear to enjoy life very well outside of the asylums. Any decent person ought to go mad if he really holds such or such opinions. It is very much to his discredit in every point of view if he does not.

All these patients suffered from similar physical conditions—they were easily tired, they were irritable, they slept badly, they suffered from headaches (often worse in the morning), and they also complained usually of backache. In these cases also the question of sexual influence often arose. In many cases he felt sure it was a part, in many it was not. Medical treatment of all such cases must in his opinion follow similar lines. They must be removed from their work because it had got to dominate them like a nightmare. They must be put under totally different surroundings and kept away from anything likely to excite the old feelings of helplessness and almost despair. He did not think that the ordinary rest cure was at all suitable for the great majority of such cases. Complete isolation often intensified the trouble; each case must be tackled as a separate problem, and the conditions as far as possible chosen which were likely to favour recovery. He could not deny that in most cases rest in bed for at least a part of the day with massage and electrical treatment were good, but he did not think that practitioners ought to be satisfied with prescribing this. They ought to see that the rest of the day was filled up with appropriate recreation, and if the patient was so ill as to need the whole day in bed then they must see to it that he was not allowed to brood, and that isolation was not thrust upon him to his undoing. It was impossible to enter into the details of such treatment because, as he had said, each case must be tackled as an individual problem. In regard to drugs he pinned his faith for the most part to sedatives and stimulants, of which bromide and strychnia were the types, and he was convinced that those drugs judiciously used in such cases could not do anything but good.

Dr. T. B. HYSLOP said that the term "neurasthenia" had been gradually extended in its connotation to include so many types of psychoneurosis that it was exceedingly difficult to lay down any one line of treatment which might be of benefit to anything but the minority of cases. The extension of the term had already—as had been the case with regard to the term "general paralysis"—led to much confusion of ideas with regard to diagnosis and treatment. As a small contribution to Dr. Risien Russell's valuable and instructive paper he would refer to neurasthenia merely from a mechanical and nutritional point of view. Assuming that the more immediate cause of the neurasthenic syndromes is alteration in nutrition—and therefore function—of the cortical cells, it might be of some value fully to consider the conditions on which adequate nutrition and exercise of function were dependent. It should be recognised that the cranium and its contents were dependent upon the blood for its nutrition and repair, and that the processes of nutrition and repair were dependent not only upon an adequate mechanism of arterial supply, but also upon an adequate mechanism of venous drainage. The cranium and the pelvis held a somewhat similar relationship to the general circulation, and their contents were dependent respectively on similar conditions of arterial supply and venous drainage. That being the case, and recognising the close similarity between the two departments, it became evident how, under certain mechanical defects in the circulation, a double series of phenomena became manifest. It was an old observation that congestion of the pelvic contents is apt to be simulated in the brain, as evidenced by the nervous and mental symptoms associated with constipation. The comparison could be carried still further so as to include, on the one hand, the numerous troubles arising from congestion of the various pelvic viscera, and, on the other hand, the almost innumerable varieties of symptoms arising from delay of the venous return not only from the various orifices of the skull, but also from the cerebral convolutions themselves. Such conditions as hæmorrhoids, which were extrapelvic in site, were simulated by the various conditions of extracranial congestion occurring at the orifices of egress of the cerebral and cranial veins, either singly or in relationship to the cranial nerves and the special organs of sense. It would readily occur to all present how, under conditions of lowered blood pressure, a tendency to venous stasis might readily occur, and, viewed from the purely mechanical standpoint, the indications for treatment were evident. In his Croonian lectures on the Degeneration of the Neurone (1900) Mott made some extremely valuable observations in regard to the part played by venous congestion in the production of various forms of nervous and mental diseases. He there pointed out the means whereby a vicious circle becomes established by conditions which tend, on the one hand, to perpetual venous congestion in certain regions, and, on the other hand, to increased excitability of the neurones, these factors mutually interacting. It seemed to be a remarkable fact, that whereas much attention had been paid to the question of the arterial supply to the brain, the venous drainage from the various convolutions had been somewhat neglected. This was all the more remarkable in view of the close relationship between the veins and their surface of drainage from the various convolutions. When one considered the question of the vital importance of an effective drainage from the various sensory and motor regions it became difficult to avoid recognising that many of the groups of symptoms met with in neurasthenia were not only of localising value, but also formed indications as to the treatment necessary. He thought, however, that this was not the occasion further to elaborate the observations of Mott with regard to the part played by venous congestion regarded from a regional point of view, but he believed that the time was not very far distant when many of the types of neurasthenia would come to be regarded as being due to local conditions of a mechanical nature, and dependent upon factors which were entirely extracranial in origin. The tendency to perpetual venous congestion in certain regions, referred to by Mott, was markedly exemplified in some parts of the course of the superior longitudinal sinus and in the area drained by the great anastomotic vein of Trolard. Just as the left middle cerebral artery was the artery of greatest wear and tear, so certain veins were subjected to greater exercise of function than others, and it was to the efficient drainage from these veins that more attention might with benefit be given. Speaking generally, he might state, with some degree of truth, that oftentimes what had come to be regarded as a familial neurotic taint was merely a familial defect in the bodily mechanism, whereby individual members of the family, whilst possessing finely evolved brains, were prone to neurasthenia because their brains were but imperfectly served by the bodily mechanism. The practical indications for the treatment of such cases were very clearly defined, and he had found benefit to accrue from complete rest of the areas which were drained defectively. One general principle of treatment was to increase the force of the arterial wave by cardiac stimulation, and to favour the venous return by aiding the inspiratory venous suction by forced inspiration, *plus* passive pressure or massage, extending from the occiput downwards. Abdominal massage was also of considerable value, and more especially so when it served to stimulate intestinal peristalsis. With regard to the special senses, he would give only one example of the effects of treatment by complete rest. The temporo-sphenoidal convolutions were particularly prone to suffer from venous stasis, and in order to give them complete and absolute rest, and more especially when auditory disturbances were present, he recommended for that purpose plugging of the meatuses by suitably devised plugs of paraffin wax. By this method he had afforded relief from hallucinations of long standing. Time would not permit him to discuss the relative values of the various methods adopted to overcome or neutralise the effects of toxins generated within the body, although, in his opinion, such considerations must in most cases go hand in hand with those to which he had already so briefly alluded.

Dr. T. GRAINGER STEWART said that he would like to associate himself with Dr. Taylor and Dr. Hyslop in expressing his appreciation of Dr. Risien Russell's paper. He would have felt happier had Dr. Russell defined what he included under the term "neurasthenia." It was true that they all understood what was implied by the term, but it was none the less difficult to define it. Those who had attempted to do so had either made their definition so wide that it included mental disorders entirely distinct from neurasthenia, but of which neurasthenia was a symptom, or, on the other hand, had so limited it as to exclude those cases in which neurasthenia had become grafted on to some distinct physical disorder. The most limited definition was that which had described neurasthenia as a primary fatigue neurosis, and if this were accepted it would of necessity imply that in all cases neurasthenia was an acquired neurosis. Personally, he preferred to use the term neurasthenia to denote a mental and physical state characterised

by symptoms, some objective, others subjective, arising in association with many different conditions, mental and physical, but independent of any recognised lesion of the nervous system. It was not, he thought, justifiable in the present state of their knowledge to consider neurasthenia as a disease—the different ways in which it might originate, the variations in its manifestations, and the totally different methods of treatment which might result in its cure all pointed to its being a state of mind and body rather than a definite disease. In treating neurasthenia, therefore, they could recognise it as a condition, not as a disease—a condition which might develop in association with grave mental or physical disease or with minor or functional disturbances in the mental or physical health of the patient. He did not consider that it could ever be held to be purely physical and rarely, if ever, purely mental, but in order to classify the types of neurasthenia they were obliged to fall back upon what, as far as could be determined, was the primary cause in each case. This might only be discovered after the most prolonged and careful examination, and such examination was necessary, not only to find out the cause of the neurasthenia, but even more to give the patient that confidence in his medical attendant without which all treatment might prove unavailing. Investigation would reveal cases which arose from (1) physical disease, exhaustion, or functional disorder; (2) mental disorder or fatigue associated with anxiety or worry; and (3) trauma with or without evidence of physical injury. Although neurasthenia might originate in physical or mental disease, or exhaustion, or from trauma, it was never complete until an element of doubt or apprehension became added to the original symptoms. The patient who had some physical disorder might suffer from exhaustion or fatigue and from loss of brain power without being neurasthenic. Similarly, in cases of overwork the patient was conscious that he could not work so well as formerly, that work was more difficult, and he might experience a sense of fulness or pressure in the head and yet not suffer from neurasthenia. In traumatic cases hysterical symptoms might be present immediately after the injury, but neurasthenia rarely developed within from three to six weeks. In all these instances the neurasthenia arose when the element of doubt began to fix itself in the patient's mind; fear that he might not recover his health; that his mind was giving way. Such apprehensions might at first be almost unconscious, but became more insistent, and as a rule the patient kept them to himself until obliged to seek relief by confiding in his medical attendant or his friends. In order to render treatment efficacious it would not suffice merely to cure or remedy the physical condition; in addition to that, the patient must be made to understand that the symptoms he complained of were due directly or indirectly to some definite cause, and that with its removal they would disappear sooner or later, as the case might be, and that he would regain his normal state. Such an explanation would only be possible or acceptable if the examination had been as complete as even the patient desired. The medical practitioner had to deal with neurasthenia in its early stages often at a time when it was impossible to tell whether the symptoms were indications of some grave disorder or not. In such instances he might not in his own mind have decided as to the nature of the case, and few people possessed the gift of dissembling their doubts from an anxious patient. For this reason it seemed to the speaker that the specialist had an advantage over the general practitioner in treating such cases. He came into the case at a time when the diagnosis might be quite simple, he had the benefit of the practitioner's experience and knowledge of the mental and physical state of the patient, and had the opportunity of making a prolonged and careful examination, and, finally, of expressing an opinion which the patient was more or less prepared to accept with confidence. It would be superfluous to attempt to add anything to the excellent and comprehensive summary which Dr. Risien Russell had given them as to the indications for the various forms of treatment to be adopted in different cases, but whatever method might be adopted he felt sure that the secret of success lay chiefly in gaining the confidence of the patient and in disclosing to him what was the actual cause of the symptoms in his special case.

Mr. DONALD J. ARMOUR said that his object in intervening in the discussion on the treatment of neurasthenia was to draw attention to, and to lay stress upon, the necessity for a fuller and more rigid treatment in the early stages of those surgical conditions which, when not so treated, were, as a late result, such a prolific cause of neurasthenia. And on this account his remarks, strictly speaking, had more to do with the prophylactic treatment than with treatment proper. In his experience there was a widespread lack of appreciation amongst medical men of the necessity of treating head injuries, especially those apparently slight in extent, rigidly and for a sufficient length of time from the occurrence of the accident, if the patient was to be prevented from developing later into a neurasthenic. Indeed, it would be obvious that the milder forms of head injury might in the end have graver results than the severe cases, inasmuch as the latter would, by the very nature of their grave symptoms, demand and obtain a more rigidly enforced treatment from the very beginning. And it was the milder forms, especially if unconsciousness had been completely absent or only transient, which owing to the slightness of the symptoms were either treated for too short a time or even escaped treatment altogether. In such cases the subsequent development of neurasthenia was undoubtedly due either to neglect of all treatment or more often to the failure to continue proper treatment long enough. Too much stress could not be laid upon the necessity for immediate and continued treatment in this class of case if complete recovery was to be obtained. Incomplete recovery sooner or later spelt neurasthenia, and a neurasthenia of a most chronic and intractable type. It was no part of this discussion to enter in detail into the treatment of such injuries. His object would have been obtained if he had impressed upon his hearers how important it was to recognise that every case of head injury, however slight, if insufficiently treated, became certainly a case of neurasthenia before a year was out.

Dr. LEONARD G. GUTHRIE spoke of neurasthenia in early life. He believed the condition was far more frequently innate than acquired. The term neurasthenia implied not only readily induced exhaustion, but also supersensitiveness to stimuli and excessive reactions thereto. Mental, emotional, and even physical development depended upon stimuli derived from the external world and conveyed through the organs of sight, hearing, taste, smell, and touch to our brains, and also to a less extent upon stimuli originating in our internal selves. An individual born bereft of all capacity to appreciate and react to stimuli would be but an inert mass of protoplasm. All individuals varied in respect to this capacity, and the neurasthenic varied in the direction of excess. The neurasthenic child showed intolerance of sights, sounds, tastes, and smells which the normal child endured with equanimity. Hyperæsthesia on the physical side was shown by exaggerated reflexes, tics, spasms, tremors, and convulsions induced by trivial causes, and by abnormal severity of symptoms attending simple ailments. Hyperæsthesia was shown by cutaneous irritability, by the ease with which emotions were aroused, and by an excess of "feeling tone," pleasurable or otherwise, induced by "negative stimuli." In all cases hyperæsthesia and excessive reactions to stimuli led to fatigue and prostration. Neurasthenia had no known pathology, but probably depended upon cortico-thalamic derangement, for it had been shown that lesions which cut off the thalamus from cortical control were attended by emotional hyperæsthesia and excess of "feeling tone" on the affected side. The rôle of the sympathetic was important, for the experience of emotions was entirely dependent upon its action, and hardly any symptoms of neurasthenia and hysteria were unassociated with sympathetic disturbance. In regard to treatment hypersensitiveness could be mitigated, though it could not be annihilated. There was a difference between keeping a neurotic child in cotton-wool and allowing him unlimited opportunities of exhausting himself mentally and physically by expenditure of energy. One was usually consulted on account of the neurasthenia itself and not on account of the excitability and irritability of temperament which gave rise to exhaustion. Rest for mind and body was essential, but in order to secure it tact and ingenuity were required on the part of the physician and the patient's relatives.

Dr. MAURICE B. WRIGHT said that his own contribution towards this discussion would be a very brief consideration of the mental factor in cases of neurasthenia and the possibility of the alleviation of the condition by any method of

psychotherapy. There could be no question that, running parallel to the general functional asthenia, there was evidence in almost every case of a disturbance of the hi gher psychical centres, disorders of memory, of attention, of concentration, and of will, and, most important of all, a marked emotional disturbance or of the affective states—a diminution of the power of feeling pleasure in any direction, an increase in the range and depth of the depressing emotions. After everything had been done from the physical side to restore a patient to health, there was often a residuum of mental symptoms which could only be dealt with by definite psychotherapeutic procedures. True neurasthenia was hardly ever suggestible to any great extent, but, apart from suggestion in the passive or hypnoidal state, he believed much could be done by steady, methodical mental re-education, education of attentive control and of interest, and perhaps, above all, by a steady painstaking explanation of the importance of such factors as expectancy and disordered attention to bodily functions and sensations, in the production of the various sensations and physical and mental disabilities. The various phobias and obsessions were often superadded to the neurasthenic syndromes, and although he did not personally believe that they had the same etiology as pure neurasthenia, they very often complicated the disease and rendered treatment more difficult. It was in the treatment of phobias and obsessions that psychotherapy in its widest sense more particularly applied. Suggestion in the hypnotic or hypnoidal state might, he thought, be employed with success in many cases, but in addition there should be a careful, painstaking endeavour to find out the causes in the psychological history of the patient which had tended to produce the phobia or obsession. He could not agree with Freud that it was necessary to go back to infantile sexual trends, but be believed firmly that there had been some *vera causa* for every phobia and obsession in the past mental experience of the patient, a *vera causa* which, if only we could demonstrate it to the patient, would enable him to free himself of the mental pain and distress of obsessional ideas. The anxiety states must, he thought, be differentiated from neurasthenia, although they might complicate the disease. In the consideration of this condition he agreed entirely with the Freudian school. In all true anxiety neuroses that he had seen the etiological factor had been apparently some abnormality of sexual life. Suggestion might be of service in these cases, but he thought the main line of attack should be in endeavouring to get the patient to return to a healthy *vita sexualis*.
